Red hematite is one of the most valuable of the ores of iron, as from it is made a large proportion of the finer varieties of iron and steel. The samples from the Napa mine (now on exhibition at the First National Gold Bank and at the real estate office of Woodward & Taggart in this city, and at 208 Montgomery street, San Francisco) are of foliated or micaceous structure, very compact laminae, are of great purity, and singularly free from sulphurous, phosphoric and argillaceous substances. Nearly all the Bessemer iron, and the finest steel manufactured in England and America, are made from red hematite of less purity than the specimens we have seen from this mine.

The importance of this discovery can scarcely be overestimated, inasmuch as another discovery, recently made by a gentleman of this city, whereby iron ore can be reduced by the use of crude petroleum at much less cost than by the use of coal, can be utilized in building up an industry of great moment to this coast, and in supplying the Pacific States and Territories with an excellent article of iron and steel, for which we have heretofore been compelled to pay out millions annually to the Eastern States and Europe. It is said, also, that within the past six months large deposits of coal suitable for coking and the reduction of iron ores, have been discovered on the northern coast.

New Motive Power.

Speaking of the boundless possibilities of invention, the Boston Commercial Bulletin says: For a long time it was thought that continued mechanical progress was in great measure dependent upon the duration of the coal supply. But of late there has been a growing feeling that discoveries will be made by which a motive power independent of fossil fuel will be brought to light.

These views received strong support at the recent meeting of the British Association at Sheffield, particularly in the lecture given by Prof. Ayrton, on electricity as a motive power. Machinery in the hall was put in motion driven from power derived from a distance. By the use of electricity the waste of power in transmission could be reduced for any distance to not more than 30% of the whole power absorbed at the generator, so that the employment of steam engines of vast size outside a town like Sheffield would be by far the most economical means of extracting the energy out of coal.

Small steam engines were told were the most expensive, for it was at least four times as expensive to produce power from them as from large ones. But electricity not only produced motive power, but heat and light, and by it they could heat from a distance a coil of iron wire white hot, and by putting it into a vessel filled with water the latter in a short time would begin to boil. Here we have simplicity itself in the generation of steam. In connection with power, the question of cost is a most important one, and in this there is a great advantage in favor of electricity, which could be sent down to where it was required, the same as gas or water, and regulated as easily. As to light, it appears that if there was a large quantity required in one place, that by electricity was 20 times cheaper than coal, whilst Sir W. Thompson went so far as to say that it might be made 133 times cheaper.

THE LOTUS IN NEW YORK.—At the recent exhibition of the New York Horticultural Society, Mr. E. D. Sturtevant, of Bordentown, N. J., exhibited three water lilies, which promise to have great practical value for decorating grounds where there are small lakes. One of the plants was a true Nilotic Lotus, with circular leaves extending above the water, similar in appearance to those of our native *Nelumbo luteum*, and showing large nodding flowers. There were also some cut flowers of the *Nymphaea dentata*, a large flower of purest white—an enlarged copy of our own white water lily, *N. odorata*. Another was a blue variety, and most striking of all was a hybrid from two Indian varieties. The large heart-shaped leaves of this plant floated on the surface of the water, while the flowers were of a delicate pink shade. Mr. Sturtevant declared that these flowers, as well as those of the *N. dentata*, were fully 12 inches in diameter during the warm summer weather. These plants were all grown in the open air.—*Scientific American*.

TELEGRAPH IN BRAZIL.—The Brazilian government has presented to the Legislature a project for establishing a general system of telegraphs, to spread all over the republic like a network, and to be placed in immediate communication with the public offices.

USEFUL INFORMATION.

Borax for Salting Butter.

The Italian Minister of Agriculture has addressed a communication to the Chamber of Commerce of Milan relative to experiments in salting butter with borax which have been carried out at the agricultural station at Florence. From the account which appears in the *Giornale di Agricoltura*, borax would appear to have a most marvelous effect in insuring its absolute preservation. Samples of fresh butter made at the Florence station, and purposely not carefully freed of their buttermilk, were found, on the addition of about 8% of borax, to maintain their natural fine flavor, without the least change whatever, for upwards of three months. To attain this satisfactory result it is necessary that the borax should be perfectly dry and in very fine powder, and care must be taken to insure its thorough mixture with the whole mass of the butter operated on. Among the further advantages of this plan, it is noted that borax imparts no flavor of any kind to the butter, while it is entirely harmless in its nature, and also reasonably cheap. Still later experiments have shown that a very much smaller proportion of borax suffices to produce the desired effect, and also that simple solutions of the salt act quite as well as the dried powder.

It has been alleged that too much borax imparts a bitter flavor. This might be lessened by washing in water. The main point is that if borax should prove a useful preservative element for butter, meats, etc., the borax industries of Nevada might be very properly advanced.

ISINGLASS FROM SEA WEEDS.—A very interesting product, called "kanten," or vegetable isinglass—a species of gelose derived from either of the sea weeds *Gelidium cornutum* or *Plocaria lichenoides*—is made in China and Japan, and exported to Europe in flat and molded tablets and in bundles of strips. It is known in Cochinchina as "hai thao." It is soluble in boiling water only, of which it takes up about 500 times its weight. It is manufactured as follows: The sea weed, called by the native name of "tengua," is carefully washed and afterward hoiled, so as to form a gelatinous decoction, which is strained off and put into square boxes. When cool it forms a stiff jelly, which can easily be divided into squares a foot in length. The manner in which the surplus water is removed is very ingenious. The jelly prisms are exposed in the open air during a cold night, and allowed to freeze. During the day the sun melts the water which runs off, leaving behind what one might term the skeleton of white, horny substance, which is extremely light and easily dissolved in hot water; when cooled it again forms a stiff jelly. This article can be applied to many purposes—for culinary uses, for making bouillons and jellies, for clarifying liquids, as a substitute for animal isinglass, for making molds used by the plaster-of-paris workers, for hardening the same material; in short, as a substitute for all kinds of gelatines, over which it has the advantage of producing a firmer jelly.—*Confect. Journal*.

HYDROGEN A GOOD CONDUCTOR OF HEAT.—A very simple method of showing that hydrogen is a better conductor of heat than other gases, which is probably due to its metallic character, is described by Carl von Than. Two strong copper wires, several inches long, are held parallel to each other, but not in contact, by slipping over them two short pieces of glass tube, one an inch from the end, the other in the middle, and filling the tubes with plaster of Paris. The short end of the wire are bent twice at right angles, so as to be an inch apart at the ends, and are connected by a very fine platinum wire. The wires are kept in a vertical position by clamping the second tube to a retort-holder or other support. The longer ends of the wires are bent apart and attached to the poles of a battery of three or four cells. The wires being insulated from each other, the current passes through the fine platinum wire, heating it red-hot. If a bell-jar of hydrogen be held over it, the wire ceases to glow, because heat is conducted so rapidly away. On bringing it into the air again it begins to glow.

SIPHON FOR CARBOYS.—The Pharmacist gives the following from a German source: Bend two glass tubes at right angles, so that the longer end will exceed the height of the vessel, while the aggregate length of the two shorter ends shall be a few inches more than the radius of the same. These tubes joined by means of rubber tubing, and one of the longer legs furnished with a perforated cork, serve as a siphon. Fit the cork to the mouth of the carboy; provide it with another smaller glass tube, to which is attached some rubber tubing several inches in length (the same as for a wash bottle); then blow through the latter. The pressure produced in the vessel is sufficient to cause the filling of the siphon.

TO DISTINGUISH CONDUCTORS OF ELECTRICITY FROM NON-CONDUCTORS.—When the platinum wire is glowing in the air the current may be interrupted, and rods of zinc, iron, copper, silver, or gas carbon, as well as pieces of sulphur, phosphorus, glass or charcoal, introduced into the circuit. When a good conductor is inserted the wire glows; when a non-conductor is introduced it ceases to glow.

A SUBSTITUTE FOR PORCELAIN CAPSULES.—A German chemist states that ordinary crockery vessels may for most purposes be used instead of the expensive porcelain capsules of the laboratory. The glaze on some of the former is superior to that on most of the ordinary porcelain vessels, and while they cannot be used for operations requiring the application of direct heat, they will answer well for making certain ferrous and other compounds which readily stain or attack the porcelain laboratory ware commonly found. Moreover, the crockery ware can always readily be obtained, while the porcelain ware is not obtainable in suitable sizes.

TO POLISH IRON OR STEEL.—For those in the metal or hardware trades who wish to obtain that beautiful deep black polish on iron or steel which is so much sought after, all that is required is to boil one part of sulphur in ten parts of oil of turpentine, the product of which is a brown sulphuric oil of disagreeable smell. This should be put on the outside as lightly as possible, and heated over a spirit lamp till the required black polish is obtained.

METALLIC LACES.—Debray uses wires of German silver in the manufacture of metallic laces. He colors metallic foils for the same purpose by depositing upon them iridescent films of oxide of lead. Litharge is dissolved in caustic alkali and the resulting solution is decomposed by a current of constant intensity, the positive pole of the battery being in communication with the metallic surface to be coated.

GOOD HEALTH.

Memory in Different People.

M. Delauney has made a communication to the *Societe de Biologie* respecting memory as studied under various biological conditions. The inferior races of mankind, such as Negroes, the Chinese, etc., have more memory than those of a higher type of civilization. Primitive races which are unacquainted with the art of writing had a wonderful memory, and were for ages in the habit of handing down from one generation to another hymns as voluminous as the Bible. Prompters and professors of declamation know that women have more memory than men. French women will learn a foreign language quicker than their husbands. Youths have more memory than adults. It is well developed in children, attains its maximum about the 14th or 15th year, and then decreases. Feeble individuals of a lymphatic temperament have more memory than the strong. Students who obtain the prize for memory and recitation chiefly belong to the former class. Parvian students have also less memory than those who come from the provinces. At the Ecole Normal and other schools, the pupils who have the best memory are not the most intelligent. The memory is more developed among the peasantry than among the citizens, and among the clergymen than among the laity. The memory remains intact in diseases of the left side of the brain, and is much affected in those of the right, from which it may be inferred that the right side is more the seat of this faculty than the left. From a physiological point of view, memory is diminished by over-feeding, by physical exercise, and by education, in this sense, that the illiterate have potentially more memory than those who know how to read and write. We remember, moreover, better in the morning than in the evening, in the summer than in the winter, and better in warm than in cold climates. Memory is, therefore, to a certain extent, in inverse proportion to nutrition, and more than that, it is in inverse proportion to evolution, since it is greatest in those individuals who are the least advanced from an evolutionary point of view—inferior races, women, children, the feeble, etc. In short, according to M. Delauney, there is an evolution of the memory, which is first sensorial, literal, and then intelligent; but memory, properly speaking, diminishes inversely as the evolution.—*Medical Press and Circular*.

A CURIOUS FREAK.—A curious instance of partial loss of memory is mentioned in the French papers. A painter, who was visiting a friend at Sceaux, was standing on a balcony on the second floor, when he overbalanced and fell on the ground below. Every one rushed down stairs, expecting to find him dead, but he quickly picked himself up and seemed unhurt. When, however, he turned to address his friends, he could not remember their names. He had forgotten his own, and, to his utter astonishment, he also found that he could not recall a single substantive. He can pronounce, one after the other, the letters of which the names of his wife and daughter are composed, but he is unable to unite them into one word.—*Boston Traveler*.

ADULTERATION OF TIN.—The adulteration of tin with lead, antimony, or other metals, is exceedingly prejudicial to health. Tin which contains lead should be proscribed entirely by the pharmaceutical world. The lead in the block-tin worm of still finds its way into distilled waters of every description. Cisterns lined with tin that has been adulterated with lead, or contain that matter accidentally, are a source of danger to every one. Solutions, distilled waters, and other liquors preserved in such cisterns soon become charged with lead, which thus finds its way into the various pharmaceutical preparations made from them.

INSECT STINGS.—The pain caused by the sting of a plant or insect is the result of a certain amount of acid poison injected into the blood. The first thing to be done is to press the tube of a small key from side to side, to facilitate the expulsion of the sting and its accompanying poison. The sting, if left in the wound, should be carefully extracted; otherwise it will greatly increase the local irritation. The poison of stings being acid, common sense points to the alkalies as the proper means of cure. Among the most easily procured remedies may be mentioned soft soap, liquor of ammonia (spirits of hartshorn), smelling salts, washing soda, quicklime made into a paste with water, the juice of an onion, tobacco juice, chewed tobacco, bruised dock leaves, tomato juice, wood ashes, tobacco ashes, and carbonate of soda. If the sting be severe, rest and coolness should be added to the other remedies, more especially in the case of nervous subjects. Nothing is so apt to make the poison active as heat, and nothing favors its activity less than cold. Let the body be kept cool and at rest, and the activity of the poison will be reduced to a minimum. Any active exertion whereby the circulation is quickened will increase both pain and swelling. If the swelling be severe, the part may be rubbed with sweet oil or a drop or two of laudanum. Stings in the eye, ear, mouth or throat sometimes lead to serious consequences. In such cases medical advice should always be sought as soon as possible.

BRAIN WORK AND BRAIN DEVELOPMENT.—According to the *Gazette des Hopitaux*, MM. Lacassagne and Cliquet have examined, by the aid of the *conformateur*, the heads of 190 doctors of medicine, 133 rudimentarily educated, 90 illiterate, and 91 prisoner soldiers, with the following results:

		Soldiers.			
	Doctors.	Educated.	Uneducated.	Prisoners.	
Longitudinal.....	85.29	81.97	79.13	81.10	
Frontal.....	48.91	43.65	42.35	41.12	
Parietal.....	52.58	49.66	50.27	49.90	

There is thus a considerable difference in favor of the doctors, and this is especially marked in the frontal measurements. Moreover, the two sides of the head are not symmetrical—in the educated the frontal region is more developed to the left, in the uneducated the occipital region is more developed to the right. The head is larger (more developed) in the case of the educated than in those of inactive intelligence. Among the educated the frontal region is more developed in proportion than the occipital; and if the difference is greater in the occipital it is very trifling, while among the illiterate it is considerable.

THE EVILS OF SMOKING IN EARLY YOUTH.—It appears that the German government has seriously taken this matter in hand, as smoking is practised to a great excess by the youth of that country, so that it has been considered to have damaged their constitution, and incapacitated them for the defence of their country. In certain towns in Germany the police have had orders to forbid all lads under sixteen years of age to smoke in the streets, and to punish the offence by fine and imprisonment. Moreover, a Belgian physician has found, during a journey of observation and inquiry, made at the request of the Belgian government, that the too general and excessive use of tobacco is the main cause of color blindness, an affection which is occasioning increasing anxiety, both in Belgium and Germany, from its influence upon railway and other accidents, and also upon military inefficiency.

DOMESTICATION AND BRAIN GROWTH.—At the recent meeting of the British Association, Dr. Crichton Browne gave an address on the influence of domestication on brain growth. He had found by experiments that domestication had greatly reduced the brains of the duck, and he argued that men, like ducks, might be fed and housed, fenced about, and exempted from participation in the life struggle, until, like the ducks, they would depreciate in mental capacity. Their bodies might increase in size and succulence, but their brains would become stunted and withered. Disease and luxury crippled the brains. It was as true as ever that men were perfected through suffering, toil, and conflict, and it was not through affluence and comfort that genuine civilization was attained. It was the civilization, not merely the domestication, of mankind that must be aimed at.

BEST ANTISEPTIC.—Prof. Klebs, of Prague, announces that the henzoate of soda is the best antiseptic in all infectious diseases. It acts, as the experiments of the author show, very powerfully. It is claimed that a daily dose of from 30 to 50 grammes to a full-grown man will render the poison of diphtheria inoperative. The henzoate is prepared by dissolving crystallized henzoic acid in water, neutralizing at a slight heat with a solution of caustic soda, drying and then allowing the solution to crystallize over sulphuric acid under a bell-glass. Large doses do not appear to be absolutely necessary. Good results may be obtained by the daily administration of about 12 grammes.

CURE FOR BURNS.—An iron-foundry man recommends powdered pinewood charcoal as "a never-failing, speedy remedy" for burns and scalds.

TABLE OF CONTENTS.

EDITORIALS.—California Maintains Her Prestige
Abroad; Profits of Mining; Boiler Feeder; Room for In-
ventions; U. S. Geodetic Survey, 257. The Weekly; An
Evil to be Remedied; Mining Laws and Regulations; A
Visitor from Alaska, 264. Late Decisions under Min-
ing Laws; Indian Peculiarities; Recent Decisions Re-
lating to Patents, Trademarks, Etc.; The New Davis
Crusher and Pulverizer; United States Geological Sur-
vey, 265. Education of Youth; Notices of Recent
Patents, 268.

ILLUSTRATIONS.—Vertical Crank and Fly-Wheel
Boiler Feeder, 257. Indian War Dance, 265.
CORRESPONDENCE.—El Dorado Mines; Nevada
Mines, Copper, etc., 268.

MECHANICAL PROGRESS.—Weldless Chains
and Cables; Carving Attachment for Lathes; Ceramic
Pottery Art; Raising Cream by Centrifugal Force; A
Solar Engine; Marine Velocipede; Fire Extinguisher,
259.

SCIENTIFIC PROGRESS.—A Wonderful Lubri-
cant; Fusing Metals Without Fire; Animal Rubber; A
Race with Thumbs on Their Feet; The Celluloid Marvel;
The Russian Thirty-two-Inch Objective; Traveling
Stones; Carbon in Comets; Currents of Ampere, 259.
MINING STOCK MARKET.—Sales of the San
Francisco, California and Pacific Stock Boards, Notices
of Assessments, Meetings and Dividends, 260.

MINING SUMMARY from the various counties of
California, Nevada, Arizona, Colorado and Idaho,
261-263.

USEFUL INFORMATION.—Borax for Salting
Butter; Isinglass from Sea Weeds; Hydrogen a Good
Conductor of Heat; Siphon for Carboys; To Distinguish
Conductors of Electricity from Non-Conductors; A Sub-
stitute for Porcelain Capsules; To Polish Iron or Steel;
Metallic Leaks, 263.

GOOD HEALTH.—Memory in Different People; A
Curious Freak; Adulteration of Tin; Insect Stings; Brain
Work and Brain Development; The Evils of Smoking in
Early Youth; Domestication and Brain Growth; Best
Antiseptic; Cure for Burns, 263.

MISCELLANEOUS.—October in the Sierra; New
Gold Fields in Tasmania; Pacific Coast Petroleum;
Eucalyptus vs. Phylloxera; The Caribou Mines, Idaho;
Weeds, 263. House Mining District, Mono County;
Globe District, Arizona; Rich Strike in Mammoth; Gold
Deposits at Folsom; Remarkable Gangue; El Dorado
and other County Mines; The Meric System, 262. Val-
uable Iron Mine; New Motive Power; The Lotus in New
York; Telegraph in Brazil, 263.

The Week.

In spite of a dull mining share market, news from mining quarters are very cheering. The late rains have enabled some hydraulics to resume to a moderate extent, and the fast accumulating snows in the mountains justify a good supply of water for spring operations. The late rise in quicksilver, owing to floods in Spain and a deficiency in the market, gives hopes that our cinnabar mines will renew their activity with the realization of good profits. Iron has also yielded to the pressure of demand and gone up in the general rush. The congratulations expressed for the return of the English sales of iron to America, have been somewhat dampened by the revelation that the market happened to be here of iron for a short time, and a moderate supply received from England was only temporary, and American producers rushed in with alacrity and stopped the importations. Lead also has felt the movement, and has been forced up, giving room for further and greater developments of the carbonate interests of Colorado. Although the supply of lead not being forthcoming to meet a sudden demand, its rise was not as prompt and steady as it might have been. Perhaps in all of the productions which are liable to sudden and peremptory demands, the motto of the producer should be "semper paratus"—always ready.

The inflow of gold from Europe continues, and European bankers are vainly endeavoring to devise means of stopping it. The Indians are committing depredations in New Mexico, and our exchanges of Montana are advising their readers to buy shot-guns, as well as more peaceful implements. In general, prosperity may be said to be returning, although slowly, and we feel confident it will be our pleasing duty to record hereafter increasing trade.

An Evil to be Remedied.

It seems to be an unfortunate characteristic of experts to "jump" at conclusions in order to justify preconceived opinions or theories. A priori reasoning founded upon assumption is very generally the basis of a multitude of opinions which are received in a more or less greater degree as they are in accordance with the desires of the individual seeking the opinion. The element of reasoning from assumption is a very general one in our mining operations. If not, there would be less error in the expert opinion bestowed upon the public. There is for instance a certain well-defined geological knowledge about mineral deposits and veins. Not every one, even a scientific geologist can, however, without careful examination, ascertain correctly whether a particular find is a mere surface deposit or a true fissure vein. The elements of nature are often perverse in their manifestations, and frequently deceive the eye of an expert. Knowledge certainly is increasing, but at the same time its glittering attendant, quackery, is not far behind. The disposition of individuals to run into abstruse theories is an advantage to that class of individuals who derive profit from the fact that mankind is engaged in a perpetual struggle towards the truth, and seize upon a semblance for the reality.

Why is it that there are so many and various opinions about the constitution of our mines? Why is it that on the one hand a mine is declared teeming with riches, and on the other hand declared to be a bumbag? Is it the fault of science that so much uncertainty exists in relation to our mines, making it almost impossible to make a safe investment? It is more the fault of ingenious deceivers who, for a consideration, will give a scientific opinion as to the value of a mine, not intending to deceive, certainly not, but appending their names as scientific experts to a favorable report upon a mine in the entire, from an assay of a well-selected specimen of ore. It is easy to detect these imposters, but there is no law to punish them. They cannot be reached pecuniarily, being execution proof, and the criminal code is silent against their deceptions. It is a pity that the damage done cannot be remedied by some modification of our laws, or that preventive measures cannot be adopted.

In relation to the opinions of experts about mining, the Salt Lake Tribune in its issue of October 18th, remarks: "There are mining doctors with cabalistic letters attached to their names, who in practice, if not in theory, insist upon their ability to see further into a grindstone, or into an uncovered and unexplored mineral vein than any man who has not graduated from the school of this mining prophets, however extensive may be his practical knowledge of mines and mining. It is times that mere scientific assumption, unsupported by practical acquaintance with mines and mining, or by painstaking examination of the mineral properties upon which it passes judgment, should be treated by mining men and capitalists with the contempt it so justly merits. If the mischief caused by these scientific blunderers was confined to the dupes who employ them, nothing need be said; but the itching desire for notoriety, if not for golden ducats, which rushes into print with volunteer and unproved statements, to the disadvantage of particular mines or districts, affects whole communities, and deserves severe rebuke."

The Tribune is moved to these remarks by an alleged false report of the Bingham gold mines, made to the London Mining Journal. The principle we contend for, in regard to all such matters, is that although scientific education cannot be otherwise than valuable as a basis of observation, yet the line must be drawn somewhere, and theory combined with practice regarded as the only just criterion of valuable opinion.

It is admitted that our mining interests are of tremendous importance, yet there is scarcely any of the occupations of life left in such a chaotic, confused condition as our mining interests. Would not the mines and mining prospects of this region be advanced by getting rid of a horde of incompetent deceivers, who either blow our mines up as solid masses of precious metals, or run them down as worthless trash? We must strike a medium, and that medium may be very properly arrived at by the establishment of a regular school of mines, the mining engineers of which shall be experts in the true sense of the word, whose acts shall be supervised by the application of some such law as that now in force in this State with reference to medical doctors. In this case, the necessity of reducing the mortality rate, which had fearfully increased through the malpractice of incompetent quacks, was the main lever which moved the Legislature to adopt such stringent measures.

Next in importance to life stands the property, and it is not only policy but duty on the part of lawmakers to prevent its loss through the false representations which may be made by parties supposed to know the truth. There is no doubt but the purchaser must be on his guard; but if he has not the requisite ability to judge for himself, he calls in his own expert—who misleads him equally as badly as the seller. The abundant evidences which show the deceit and representation in regard to our mining interests show the necessity of some counteracting influence to protect the community who

seek investment. Great injury has already been accomplished by the spirit of "laissez aller," and bad repute will certainly affect us in the future. If the law is competent to provide a punishment for the swindler of every-day life, it is abundantly able, by preventive enactments, to deprive the theoretical mining expert or swindler of his influence, and compel him to acquire proper knowledge of his business, or to drop out of sight.

Mining Laws and Regulations.

In early days in California when mining was confined merely to surface washing with the pan and rocker, it was found necessary to establish certain rules among the miners defining the qualifications of an individual worthy of holding and working a claim, and restricting the size of each claim, in order to give as many as possible a chance to reap the golden harvest. These rules were few and simple, and varied with circumstances in different localities. They were for the most part suggested by an innate sense of right and wrong and common justice, and were recognized and adopted by the common consent of the miners themselves and no other class.

These laws and customs appeared to work with such entire satisfaction to all parties concerned that they are even now sometimes referred to as models of legislative wisdom, but they were probably no wiser nor better than similar claims that would again be adopted under the same conditions. Their objects were extremely simple, and the individuals who made them and were governed by them fully understood those objects. In case of disputes, the parties disagreeing did not refer to a musty mass of precedents, but appealed first to their common sense of justice, and if that failed to settle it, a decision by arms was apt to be the next step, and, appreciating this, men were slow to inaugurate a quarrel. The defeated party in a suit of that kind never afterward complained of defective laws, while the victor, of course, had no occasion to; but could those who suffered injustice by our primitive mining laws rise and explain their cases, it is probable that our respect for those laws would be greatly diminished.

That style of enforcing laws has, however, become nearly obsolete, and as it faded out sharp practices grew apace. Dishonest slysters, no longer fearing the quick decisive arbitration of the revolver, were only too ready by ways that were dark to steal the property of the simple but honest miner and prospector. Not only has the tendency to summary justice died out, but all other conditions have greatly changed. Mining, from being but the temporary pursuit of a few thousand hardy adventurers who followed but a single branch of it in the most primitive style, has become the leading industry of a great people on this coast, and, as the time changed, the necessity of corresponding changes in the mining laws has been felt. The attempts of Congress to meet the requirements have been founded upon the necessities of the case, and have been partially successful. It was urged upon that body that the local rules and regulations that had always prevailed among the miners operated so satisfactorily that any disturbance of them would be injurious to the interests of the people, and this argument was given such weight that Congress, apparently fearing that it might conflict with established local customs, passed an act—the act of May 10th, '72—now alleged to be inadequate, to meet new questions constantly arising. Except, as to those sections relating to patents to mineral lands, the idea seemed to be merely to establish a few general rules for future guidance in locating and holding claims, while details were left to district laws to provide for.

As Congress has organized a public land commission, a part of the duty of which is to investigate the working of the present mining laws and suggest improvements, a consideration of some of the deficiencies of the present law is now of general interest. One of the most apparent deficiencies of the law as it now stands, is that it places no limit on the number of locations and the amount of mineral land a single person can hold. It does not even prohibit the same party from making two locations on the same vein. The consequence is that whenever any new mineral-bearing section is discovered, every piece of ground that has even a suspicion of value is immediately seized by the first comers and held for sale to those who may arrive later. It is not uncommon for a single set of men to hold from 25 to 200 claims for a whole year without doing a single stroke of work toward their development, the only item of expense being a matter of one or two dollars each for recording. The prices at which such claims have been held has usually been so high as to prevent new comers, even though they were men of means, from taking any active interest in the mines, and in this way many promising districts have been crippled in their infancy, or greatly retarded in their growth. Though it might not be advisable to restrict each man to a single claim in any district, yet the limit should be somewhere within reason. We do not allow one settler to monopolize all the agricultural land he can find, and there is no good reason why we should allow one miner to grab a large number of claims to the exclusion of others just as deserving.

In Section 2320 of the Revised Statutes, we

read that "no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located." This at first glance would seem to be a good provision, but experience shows that there is a vast difference of opinion among men as to what constitutes a lode and its discovery, and as no penalty is attached to claiming a vein which is only supposed to exist, the clause is entirely inoperative. The mere cropping out of country rock or finding of a fragment of well-worn float, is often considered sufficient evidence to warrant the location of a vein. Indeed locations are very commonly made where no indications of a vein whatever exist, and the ground held in the hope that it may in some way become of value.

Another clause provides that claims shall be located and described by reference to some natural object or permanent monument such as will identify them, and that the boundaries shall be distinctly marked. But in this case also there is no practical remedy against a false or deceptive description. Notices are often recorded where the claimants have in reality not marked the boundary lines at all, or in which only vague reference is made to natural or permanent objects intended as boundaries. The object of recording them is very frequently the hope that valuable discoveries may afterwards be made in the near vicinity, and the defective claims floated over them.

The provision which allows a locator one full year in which to make \$100 worth of improvements, is usually accepted in district codes of law as being a proper and easily complied-with measure, but it is altogether too liberal and gives the speculator too much chance. At least that amount should be put on during the first three months, so that claims could not be held for considerable time for nothing and delay active mining.

But our troubles, after all, are not so much the result of defective laws. The few changes hinted at above are perhaps all that are needed in reference to locating and holding veins. The greater difficulties lie in the facts that there is a large class of men disposed to be dishonest, and that incompetent and careless men are too generally put in office, so that laws, which are good and sufficient in themselves, fall to the ground through lack of proper administration.

We cannot enforce a law requiring all men to be honest and conscientious, and when they become so we will hardly have need of any law. But we certainly can have laws which will protect the miner against the irregularities of official acts. As it is now, if the official neglects his duties the claimant is the sufferer, because the Government repudiates official delinquencies.

A Visitor from Alaska.

We had the pleasure of a call from E. Conklin, of New York, the representative of the American Press Association, who has just returned from a trip to Alaska. Mr. Conklin describes the scenery along the route as of surpassing beauty. The steamer is kept in a channel near the main land, and the voyage seems more like that along a beautiful river, narrowing in sometimes between high and woody cliffs, and then widening out into the semblance of a beautiful placid lake, fringed with timber and green-clad hills. Mr. Conklin says that there exist many errors about Alaska, both as to climate and resources. For instance, the Bay of Sitka is generally represented in pictures with natives spearing walruses, and a background of tremendous icebergs; a fancy picture for the reason that icebergs and walruses are unknown there. Root crops are grown to perfection. Potatoes were shown him weighing three-quarters of a pound each and 30 in a hill.

The thermometer last winter did not get below +11°, which is much warmer than New York. The Kuro Siwa, or warm Japan current which flows through Behring's straits into the Arctic ocean, exerts an astonishing influence upon the climate, the isothermal line of which would probably be about the latitude of Philadelphia.

Thirty miles from Fort Wrangel up the Stiklen river, exists the only living glacier in America. It is fully 60 by 20 miles, and its progress may be watched from day to day. The whole country is immense and its climate varied. The climate of the frigid zone may be found away to the northeast, while that along the coast is moderately temperate, the interior varying as the influence of the sea diminishes. The mines are about 23 miles from Sitka and are regarded as true fissure veins, the ore is, however, low grade. The mining is generally by means of tunnels run into the sides of the mountains. Probably 500 miners are engaged in mining, which can easily be carried on for five months of the year. Sitka is a general rendezvous for the population, which is of a floating character, prospecting in the summer and returning to the town in the winter.

A regular trade is springing up between the Pacific coast and Alaska, and its resources are gradually assuming great commercial importance. Mr. Conklin, in a new work entitled "Picturesque Northwest," to come out in May, will fully describe this region and introduce some valuable engravings of scenery, etc.

THE miners on a strike at Charleroi, Belgium, are returning to work, the Socialists advising them to defer the strike until the men in all the pits can join it.

Late Decisions under Mining Laws.

The Acting Commissioner of the General Land Office, M. Armstrong, has issued instructions to the Land Offices as follows. "You will refuse to receive any papers certified, sworn to or subscribed before a notary public who is United States deputy surveyor—mineral or others."

The reason of the instruction, which must be regarded as a "ruling," arises from the fact that the Legislature of Montana has authorized the Governor to appoint United States deputy mineral surveyors as notaries public in matters pertaining to mining claims, public or private lands, etc., the Surveyor General applied to the Commissioner of the General Land Office to know what he shall do about it, Acting Commissioner Armstrong responds in no equivocal terms that the thing cannot be done.

Section eight of the act of Congress entitled, "An Act to provide a temporary government for the Territory of Montana," approved May 26th, 1864, provides: "And no person holding a commission or appointment under the United States except postmasters, shall be a member of the Legislative Assembly or shall hold any office under the government of said Territory."

The deputy surveyors are mineable through the Surveyor General to the supervision and control of the General Land Office, and are clearly officers by appointment under the United States, and the office of notary public is an office under the government of Montana Territory. The offices are practically antagonistic, as it was probably intended that the offices of the United States should be under the exclusive supervision of the Government, which would not be the case if holding a State or Territorial office. The act of the Legislature of Montana is in plain violation of said law of the United States, said Territorial Legislature is not only in excess of the power granted, but in direct contempt of an express prohibition.

The decision in the case of the protest of Central City, Golden Gate and Archer City (all said to be portions of Deadwood, Dakota), against the application for patent of James Pierce *et al.*, to a placer claim, is a protection for mining lands as against town sites. The Acting Commissioner in his decision says:

"I am of the opinion, from the testimony, that the land involved should properly be claimed as valuable for minerals." The testimony in the affirmative is direct and explicit, while that in the negative at the most but denies that the land is sufficiently rich to be worked with profit, and is based upon statements made to witnesses by third parties.

It appears from the decision of the Secretary of the Interior, in *re* Thomas Starr to enter as placer mining certain tracts in Leadville, Colorado, that the land should, under the provisions of Section 2318 Revised Statutes, be held as "valuable for minerals," and should be reserved from sale except as provided by law regulating the sale of mineral lands, and said: "In my opinion, the evidence submitted as to the relative value of the land for town sites or mining purposes was improperly allowed. If the land was mineral, it was subject to location under the provisions of the mining law, without reference to the relative value of a portion of the tract for township purposes."

This decision, says the Acting Commissioner in the Deadwood case, relates to placer mining ground only. A different rule obtains under the Statute and the decision of the Department in the case of town sites located on lode claims, and in such cases reservations are inserted in the respected patents. The land in question in this controversy is plainly mining ground and valuable as mineral. "I decide that it is not subject to town-site entry or to any disposition whatever, except under the provisions of the mineral law. I conclude that the patent in this case should be dismissed, and the land held subject to sale as mineral, with 60 days to appeal from this decision." The Acting Commissioner also decided recently the following points:

All lands belonging to the general Government in Missouri and Kansas are subject to being entered as agricultural lands.

Lands containing valuable deposits, except in veins of quartz and rock in places, are subject to being entered as placers.

No locations of mining claims can be made on the Petaca Grant, or any other land held under Spanish or Mexican titles obtained before annexation.

The patent approved and issued last May to Jose P. Azivida, for W. $\frac{1}{4}$ N. E. $\frac{1}{4}$ 32, and N. W. $\frac{1}{4}$ N. W. $\frac{1}{4}$ 33, 2 N. 14 E., at Stockton, California, as agricultural land, has been withheld for investigation at the instance of W. Gaynor mining company, upon an allegation not only that it is mineral, but that it has been worked as mineral land for 15 years.

A party who discovers and locates a mineral claim, and subsequently makes another discovery on the same claim, or finds lode number two to run across his first location, can locate the second claim and hold both, there being no conflict with other parties at date of location; or he can abandon the original location and make another, in case the new vein discovered falls outside of his first claim. The above opinion was given in a Utah case, where the discovery of the second lode was within the limits of the first location.

It is proposed to offer in Congress an amendment to the land laws, so as to make an individual caught in the attempt to obtain Govern-

ment land by false representations forever disqualified as a pre-emptor under the homestead or any other law.

Indian Peculiarities.

Theaborigines found in America by the discoverers were termed Indians, because the objective point in voyages to the West was India, and hence when the Western Continent was discovered it was hailed as the long-sought-for country of fabulous wealth and mystery. In many respects the manners and customs of the Indian tribes showed evidences of a tradition which must have descended to them from the human race in Asia. Their religion, theory of origin and acquaintance with the events related in the Bible, and of general mythological belief among the Asiatic nations, show a remarkable similarity. One element in Indian customs remarkable for its similarity to the peculiarities related of the more civilized nations of the old world, is that of dancing upon occasions of joy, sorrow or war. In all, however, there is a natural grotesqueness which is supposed to indicate the ideas thought to be indicative of the sensations or of preparation for some important event. The feeling is natural, even the white man is desirous of "dancing for joy," and uses the expression, when the Indian practically demonstrates it.

The solemn religious dance of the Hidudo

INDIAN WAR DANCE.

finds a parallel in the sun dances of some of the Indian tribes, and is even perpetuated in the dancing feature common among the Shakers of civilization. In the war dance of the Indian, which we illustrate on this page, the grotesque and horrible form a dreadful accompaniment which even to a savage mind can be excused only by the dread uncertainty of the war to follow the uncouth ceremony. The devil is particularly materialized for the occasion and the enemies of the tribe turned over to his domain, while the wild bull of the happy hunting grounds is propitiated in the hope that his prototypes in the opposing camp will become the loot of the victors.

Very much of the Indian character and origin may be learned from the meaning of even the simplest dances. David danced before the ark, and perhaps the savage dancing before the image of some unknown divinity, demonstrates an origin which the most profound researches of scientific men in regard to prehistoric remains dare not contemplate.

ATTENTION is called to an important advance in refined sugar and syrup. Local refiners are keeping up with the advance in the New York market. They now have the field well in hand.

In San Francisco half dollars are quoted at 99 $\frac{1}{2}$ buying 100 selling; trade dollars, 95 buying, 96 $\frac{1}{2}$ selling; Mexican dollars, 91 buying, 92 selling.

GENERAL MERRITT has been ordered from Washington to suspend operations against the Utes, pending negotiations for peace.

Recent Decisions Relating to Patents, Trademarks, Etc.

U. S. Circuit Court, Western District of Pennsylvania—Couse & Blood vs. Johnson, Black & Co. Decided Sept. 25th, 1879.

1. The claims of a patent ought not to be expounded constructively beyond the limitations which the patentee has imposed upon them so as to cover subsequent improvements in an art in which the invention claimed was, at most, only a step in advance.

2. The patentee's exclusive right is enforceable only within the limits of his own definition of it.

3. Where a claim is not limited to a particular form or construction of device, and the specification does not assign any peculiar merit or claim any new result as the product of its conformation, such form cannot be considered as an essential part of the invention.

4. Where the subject of a claim is of doubtful patentability, and the specification vague with regard to it, the patentee cannot make a valid claim for it.

5. The application of old mechanical devices, without material change, to a use in which they were not employed before, but which was known and had been practiced, does not constitute a patentable invention.

6. The use by complainant of kerosene oil in a

invention contained in the original patent, and when, in a suit between the same parties, the Supreme Court of the United States had decided that the defendant's apparatus did not infringe a valid reissue thereof, and the suit was accordingly dismissed.

2. The omission in a reissue of an element essential to the invention as originally described and patented, is fatal to the reissue.

3. Reissued patent No. 6,249, granted to Samuel Lewis, Jan. 26th, 1875, for improvement in apparatus for removing obstructions under water, is invalid.

U. S. Circuit Court, District of New Jersey—Spring, *et al.* vs. The Domestic Sewing Machine Company. Decided July 17th, 1879.

1. A decree by the court, made at the request and in accordance with an agreement of the parties litigant, not effective against others not parties thereto.

2. A decree by consent of parties litigant should have very little weight in any court, when produced as an adjudication in favor of the validity of a patent.

3. Two years' use by defendant of the complainant's patent, with the latter's knowledge, who took no steps to stop it, is sufficient to defeat a motion for a preliminary injunction.

4. Complainants are chargeable with the laches of the former owners of the patent, having succeeded only to the rights of such former owners.

The New Davis Crusher and Pulverizer.

In company with the inventor, Mr. John T. Davis, we visited this week the Golden State and Miners' foundry, to examine the new form of crusher and pulverizer to be seen at work there. The machine is an ore crusher and pulverizer combined, and has three distinct motions combined in one—the *eccentric*, the *rotary* and *vibratory*; and by this combination a large amount of work is done with a small machine. The ore is fed in at the top, through a hopper, and passes down through the machine and out at the bottom, where it drops on a screen, which regulates the fineness, the coarser particles going back into the machine with the broken ore. The machine in operation will take in pieces 4 inches square.

We saw the machine working dry, but the inventor says it works quite as well with water, so that it will meet any case, but will do the most work in a dry state. It can be made cheaply, so that any person having a good ledge of ore can arrange to have it put up on their mine. It will be especially useful for such mines as are at a distance from a large supply of wood or water.

The machine will weigh about 2,500 pounds, and cost about \$500. The body is strongly made, and so arranged that the shoes and dies are easily replaced—a full set costing only \$4. An automatic lever attached to the machine enables the operator to grind the ore to any desired fineness, from the size of a bean to a No. 90 screen—an advantage of great utility in working sulphurets or preparing ore from leaching. Mr. Davis has devoted much time to perfecting a machine which will meet the wants of the mining community, and those interested in such appliances may see this one at work at the foundry named, on First street, near Folsom. We shall shortly give an engraving of the machine, with fuller details of its construction and operation.

UNITED STATES GEOLOGICAL SURVEY.—A circular letter, dated Oct. 20th, 1879, has been issued by G. F. Becker, Esq., Geologist in charge of the Survey at San Francisco, which says: A main object of the United States Geological Survey is to advance the knowledge and practice of the mining arts by investigation and description of the occurrences of ores, of the methods employed in mining them, and of the processes by which they are treated. Every mining district will receive the attention of the Survey; the information obtained and the results of special investigations will be so presented as to afford a trustworthy record of the mineral character of the country and of its resources, and of the methods of manipulation which have proved most suitable under varying local conditions. Each district will therefore receive the benefit not only of the labors of the Survey within its limits, but of the collective experience of the whole country. Mr. Becker, very properly, requests the co-operation of the newspapers published west of the Rocky mountains, and desires his office to be placed on the free list, as the expense of subscribing to all the papers necessary and desirable for correct information is greater than the Survey can afford. Suitable acknowledgements of courtesies extended to the Survey will be made. We believe there will be a united effort on the part of local newspapers to comply with this desire, as it is the most effective means of gleanings accurate and complete information. We may state in this connection that Dr. Becker has very recently ordered for the Survey a complete set of bound volumes of the MINING AND SCIENTIFIC PRESS—making 38 volumes in all—which he desires to keep on hand for reference and as a full record of mining events in this country.

In New York Government bonds are quoted at 102 $\frac{1}{2}$ for 4s of 1907; 103 $\frac{1}{2}$ for 5s of 1881; 105 $\frac{1}{2}$ for 4 $\frac{1}{2}$ s; sterling, \$4.81 $\frac{1}{2}$ @\$4.83 $\frac{1}{2}$; silver bars, 113 $\frac{1}{2}$; silver coin, $\frac{1}{2}$ @1 discount.

U. S. Circuit Court, Eastern District of New York. Cammeyer, *et al.*, vs. Newton, *et al.* Decided March 19th, 1879.

1. A reissue to be valid must be for the same

FOREIGN PATENTS

FOR PACIFIC STATES INVENTORS

ARE SECURED IN MUCH LESS TIME,

—BY—

DEWEY & CO.,

AT THE OFFICE OF THE

Mining and Scientific Press,

THAN THROUGH ANY OTHER AGENCY.

Established in 1860,

THIS FIRM CAN BE RELIED UPON

—AS—

Honest, Competent, Permanent,

ALL OF WHICH POINTS ARE IMPERATIVELY
REQUISITE IN ATTORNEYS, FOR THE IN-
TERESTS OF THEIR APPLICANTS FOR
PATENTS IN DISTANT LANDS.

Our Associates and Correspondents are the
Best Practitioners in every country where Patents
are granted.

For Foreign Patents no model is required, as
a rule, except in Canada. The Specifications
and Drawings of the American Patent, if com-
plete and perfect, will suffice for us to prepare
the case. In Great Britain and other countries
we apply for patents in the inventors' own
names, thus avoiding their being published to
the world in the name of a foreign agent, as is
usual through other and less painstaking agencies.

Frequently several inventions, covered by
different patents in the United States, on the
same subject, can be skillfully combined in one
patent in foreign countries, when well under-
stood by intelligent attorneys.

As the privileges of our inventors are cut off
in some countries, and curtailed in others, if not
applied for soon after the issue of the U. S.
patent, we advise inventors whose patents will
be valuable in various populous civilized coun-
tries, to lose no time in applying for patents
whenever they intend to obtain them for them-
selves or the benefit of others—with their own
means or through the resources of those who are
permitted to share the benefits. It must be
remembered that the English (and some other
important nations) invite the early introduction
of inventions into their realms, by offering pat-
ents to the first introducer (which means the
first applicant), without regard to the rights of
the actual inventor, who has no after recourse.

For important inventions it is best to apply
for foreign patents at the time of application for
or before the issue of the U. S. patent.

Term of Patents in Foreign Countries

COUNTRIES.	PERIOD OF YEARS GRANTED, ETC.
Australian Colonies:	
Victoria.....	14 years in successive periods, 3, 4 & 7 yrs.
Tasmania.....	14 years in successive periods, 3, 4 & 7 yrs.
New South Wales.....	14 years in successive periods, 3, 4 & 7 yrs.
Queensland.....	14 years in successive periods, 3, 4 & 7 yrs.
N. Zealand.....	Full term, 14 years....
Austria.....	15 years, by annuities.
Argentina Republic.....	25 years or more, de- termined by govt.
Belgium.....	20 years by annuities.
Brazil.....	15 to 20 years....
Canada, (including British Columbia).....	14 years, at the option of govt.
Chile.....	25 years or more, de- termined by govt.
Cuba.....	5, 10 and 15 years....
Denmark.....	5 to 20 years, at the option of govt.
England.....	14 years, in successive periods, 3, 4 & 7 yrs.
France.....	15 years, by annuities.
German Empire.....	15 years, by annuities.
Italy.....	12 years, by annuities.
India.....	14 years, 5 copies, spec- ification required.
Mexico.....	Full term, 10 years....
Norway.....	5 to 10 years, at the option of govt.
Portugal.....	Importation 5, Inven- tion 15 years....
Peru.....	25 years or more, de- termined by govt.
Russia.....	Importation 1 to 6 yrs. Invention 3, 5, 10 yrs.
Spain.....	Importation, 5 yrs. In- vention 5, 10, 15 yrs.
Sweden.....	3 to 5 yrs, at the op- tion of government.

We have the Foreign Patent Laws, Foreign
Patent Reports, and other valuable and assisting
documents, for ready reference in our MIN-
ING AND SCIENTIFIC PRESS Patent Agency Li-
brary—the most complete Patent Library on
this side of the Continent.

The cost of patents in any one or more of the
above countries will be furnished on applica-
tion to us.

Any further information regarding the time
within which patents must be worked in any
foreign country, time of payment and amount
of annuities for patents in any of the above
countries, will be cheerfully given on applica-
tion.

Full particulars regarding any countries not
named above, will also be given when desired.

cents, postpaid. Wholesale and retail agents wanted.

THE BEST FILEHOLDER.—After having used Dewey's
patent elastic hinge fileholder for over a year past, the
News cheerfully indorses it as the best newspaper file-
holder in existence, possessing important advantages over
any and all others in use. The holders are neat, light and
convenient, and the newspapers are placed in them with
the utmost facility and least possible time and exertion.
They are the simplest, handiest and cheapest of all. Any-
body keeping files of papers in reading rooms, offices or at
home, should send at once to the proprietor, A. T.
Dewey, San Francisco, and get the only proper fileholder.
Samples by mail fifty cents.—Gold Hill News.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued,
contains the United States mining laws and instructions
thereunder, a digest of decisions, forms, list of mining
patents issued, etc. The digest of decisions alone is a
very valuable thing, giving, as it does, in brief form, all
the decisions of the Secretary of the Interior and Com-
missioner of the General Land Office in relation to mining
matters. These are all under proper headings for easy
reference. Forms are given for notice of location, proof
of labor, notice of forfeiture, miners' lien, application for
survey, patent, etc., affidavit of improvements, etc.
There is also a list of patents issued for mining claims
from July 20th, 1860, to August 1st, 1877. The book is
of pocket size and very convenient for all who are inter-
ested in mines. It will be sent post-paid for \$1, on appli-
cation to Dewey & Co., 202 Sansome street, San Francisco

SPECIMENS.

CHOICE SPECIMENS of Quartz showing native Gold,
Copper, Galena or Iron Sulphates, Pyrites or Clusters of
Crystals, or Petrified Wood sent, postage paid, on receipt
of \$1. Address

sonic Inscriptions Carefully Engraved.

Acknowledgement and Thanks.

LAKEPORT, Lake Co., Cal., Nov. 2d, 1878.
MESSRS. DEWEY & CO.—Gentlemen:—I hereby acknowl-
edge receipt of patent, for which please accept my sin-
cere thanks. When I have any further business in this
line I shall certainly employ you. With kind regards, I
am, Yours very truly,
CHAS. SLATTERBECK.

ALLEN GOVERNOR.

This Governor is now being generally adopted through-
out the United States and Europe. It is without doubt
the

Most Perfect Engine Regulator in Use.

And will in most cases save its cost several times a year.
It is invaluable on a QUARTZ, FLOUR or SAW MILL
ENGINE, or in any Manufacturing Establishment, where
Regularity of Speed is desirable. By being able to run
the engine to its full capacity, these Governors have in
many cases added

Ten Per Cent. to the Productive Capacity of a Mill.

Thus saving more than their cost every week in the
month. Every Engine to which this Governor is attached
will run with the throttle wide open. The speed of the
Engine can be changed by a simple adjustment of the
weights. It will give a UNIFORM SPEED WITHOUT
REFERENCE TO THE BOILER PRESSURE. It is simple
in construction and not liable to get out of order.
Every Governor warranted to give perfect satisfaction.
Thirty days given for a trial, and if it does not fulfill all
that is promised, it can be returned at our expense.
In ordering, state the kind of engine, diameter of cylin-
der, stroke, speed, and average pressure.
Send for full descriptive circular.

Sole Agents for the Pacific Coast,

No. 127 First Street, San Francisco, Cal.

UNITED STATES

Mineral Land Laws, Revised Statutes

AND INSTRUCTIONS AND FORMS

UNDER THE SAME.

We have just issued a pamphlet containing the General
Mineral Land Laws of the United States, with instructions
of the Commissioner of the Land Office. The contents of
this pamphlet comprise all of the Government laws with
relation to mineral lands of interest to the mining com-
munity, as follows: Mining Statute of May 10th, 1872,
with Instructions by the Commissioner of the Land Office;
Mining Statute of July 26th, 1800; Mining Statute of July
9th, 1870. Forms required under Mining Act of May 10th,
1872, as follows: Notice of Location; Request for Surveys;
Application for Patent; Proof of Posting Notice and Dia-
gram of the Claim; Proof that Plat and Notice remained
Posted on Claim during Time of Publication; Registers'
Certificate of Posting Notice for Sixty Days; Agreement of
Publisher; Proof of Publication; Affidavit of \$500 Im-
provements; Statement and Charge of Fees; Proof of
Ownership and Possession in Case of Loss or absence of
Mining Records; Affidavit of Citizenship; Certificate that
no Suit is Pending; Power of Attorney; Protest and Ad-
verse Claim; Non-Mineral Affidavit; Proof that no Known
Veins Exist in a Placer Claim, etc. There is also given
the U. S. Coal Land Law and Regulations thereunder.
The work comprises thirty pages, and will be sold, post-
free, for 50 cents. It should be in the hands of every
one having any mining interests. DEWEY & CO.,
Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT
for DIAMOND POINTED DRILLS, now brought to the
highest state of perfection, are prepared to fill orders
for the IMPROVED PROSPECTING AND TUNNELING
DRILLS, with or without power, at short notice, and
at reduced prices. Abundant testimony furnished of
the great economy and successful working of numerous
machines in operation in the quartz and gravel mines
on this coast. Circulars forwarded, and full infor-
mation given upon application.

LAND

Good land that will raise a crop every
year. Over 14,000 acres for sale in lots to
suit. Climate healthy. No drouths, bad
floods, nor malaria. Wood and water
convenient. U. S. Title, perfect. Send stamp for illus-
trated circular, to EDWARD FRISBIE, Proprietor of
Reading Ranch, Anderson, Shasta County, Cal.

PHOSPHATE SOAP

THE BEST soap for toilet use ever
manufactured. BEST because it con-
tains all the excellencies of the most
expensive foreign or American soaps
without their defects. BEST because
it combines strength with delicacy
in such a way that its strong detergent
qualities do not injure the skin.
BEST because it is the result of years
of study and experiment in the soap
manufacturing business, assisted by
modern chemical discoveries. BEST
because it contains ingredients benefi-
cial to the skin, which unite chemi-
cally with the soap in such a manner
as to increase its saponaceous quali-
ties. Every chemist familiar with
soap manufacture knows that some
ingredients which are in themselves
beneficial to the skin cannot be saponi-
fied; some are partially neutralized,
while others injure the quality of the
soap. There are soaps in the market
which are to some extent beneficial to
the skin, but they are inferior articles
for toilet use. PHOSPHATE SOAP
is the ONLY article offered to the
public which combines all the best
elements of toilet soap with medical
ingredients beneficial to the skin.

If your wife is in the habit of using
cosmetics of any kind, advise her to
give up the pernicious practice, as
the most harmless face powders ob-
struct the pores of the skin and
sooner or later injure the complexion,
while PHOSPHATE SOAP removes
all impurities and assists nature in
developing a natural, healthy and
beautiful skin.

It is an old proverb that an ounce of
preventive is better than a pound of
cure. Twenty-five cents invested in
a cake of PHOSPHATE SOAP will
save hundreds of dollars in doctors'
bills. It acts as a constant disinfect-
ant, preventing Salt Rheum and other
skin diseases.

If your wife will persist in the use of
cosmetics, buy her a cake of PHOS-
PHATE SOAP and tell her to use it
every night before retiring. In that
way much of the harm will be avoid-
ed, as the skin will thereby be able to
retain much of its natural vigor and
beauty.

No salve or ointment can heal a
wound or sore of any kind. Every
educated physician will tell you that
nature alone can do this. PHOS-
PHATE SOAP, by its cleansing,
soothing and purifying qualities, gives
nature a chance to act freely.

Natural beauty surpasses anything
which can be imparted by artificial
means. PHOSPHATE SOAP gives
health to the skin simply by removing
impurities and eradicating the poisons
which give rise to skin diseases.

Not only for daily use on the face
and hands, but for bathing the entire
body, there is nothing equal to PHOS-
PHATE SOAP. It is a thorough disin-
fectant and removes offensive odors
of every kind.

Ladies who have injured the skin by
the constant use of cosmetics may do
much to restore their faces to that
beauty which nature alone can give
by constantly using PHOSPHATE
SOAP.

For all diseases of the skin use
PHOSPHATE SOAP. There is nothing
like it for removing impurities and
giving the skin a healthy and
natural vigor.

Cheap toilet soaps manufactured
from rancid and refuse grease injure
the skin and are really more expen-
sive than PHOSPHATE SOAP, which
retails for 25 cents per cake.

Thousands of articles are palmed off
on the public which have no genuine
merit, but PHOSPHATE SOAP is the
result of modern discoveries of cele-
brated chemists.

PHOSPHATE SOAP costs no more
than other good toilet soaps, while its
medicinal qualities make it worth ten
times its price to every man, woman
and child.

If you want a nice article of Toilet
Soap and something that is beneficial
to the skin, buy PHOSPHATE SOAP.

Metallurgy and Ores.**Nevada Metallurgical Works,**

No. 23 STEVENSON STREET,
Near First and Market Streets.

Ores worked by any process.

Ores sampled.

ASSAYING in all its branches.

Analysis of Ores, Minerals, Waters, etc.

WORKING TESTS MADE.

Plans furnished for the most suitable process for working Ores.

Special attention paid to Examinations of Mines; plans and reports furnished.

E. HUNN,

C. A. LUCKHARDT,
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS,

CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNDRIES, Etc.

512 & 518 Washington St., San Francisco

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

W. BRUCKNER,**Mining Engineer,**

Will Contract for the erection of

MILLS, ROASTING FURNACES, SMELTING FURNACES, AMALGAMATING WORKS.

— ALSO —

LEACHING WORKS,

With all the Latest Improvements. Address

STATE ASSAY OFFICE,

Safe Deposit Building, Room 16, San Francisco.

E. W. RIOTTE, D. KUSTEL, GUIDO KUSTEL.

METALLURGICAL WORKS,

318 Pine St., (Basement),

Corner of Leidesdorff Street, - SAN FRANCISCO

Ores Sampled and Assayed, and Tests Made by any Process.
Assaying and Analysis of Ores, Minerals and Waters.
Mines examined and reported on.
Practical instruction given in Treating Ores by approved processes.

G. KUSTEL,

E. N. RIOTTE,

524 Sacramento St., S. F.

PIONEER REDUCTION WORKS.

G. F. DEETKEN - Manager.
Channel Street, off foot of Fourth, San Francisco, Cal.

Highest price paid for Sulphurets, Arseniurets, Tellurides and Gold Ores generally.

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SCIENTIFIC PRESS ENGRAVING CO.,

No. 202 Sansome St., S. F.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosbie and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of OROSS & CO., San Francisco.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed under-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from scouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

Mines and Works of Almaden.

Translated from "Annales des Mines"
By S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

AN ENGINEER,
Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

OBTAINED IN U. S. AND FOREIGN COUNTRIES; trademarks, labels and copyrights registered through DEWEY & CO.'S MINING AND SCIENTIFIC PRESS Patent Agency, San Francisco. Send for free circular

Machinery.**GOLD AND SILVER****Grinding and Amalgamating MACHINERY.**

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

**SPERRY'S****Wrought-Iron Frame FOR STAMP MILLS.**

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

[CONTINUED FROM PAGE 261.]

I. X. L. DISTRICT.

NEW MINES.—D. R. Seaborn, in the Carson *Appeal*, says of this new district: "Good mines have been found in Churchill county, in a range of mountains 12 miles west of La Plata. One miner ran a tunnel 20 ft long and struck a ledge 30 ft wide, which has not yet been penetrated. Some of the ore is pure silver. There is an abundance of wood and water in the vicinity. Since the discovery of that mine, eight square miles of timber have been taken up. There are now about 50 men at that place, principally from Eureka."

PARADISE DISTRICT.

MARTIN CREEK.—The editor of the *Reporter* visited the Paradise Co's new mill at this point and pronounces it one of the finest and best regulated ten-stamp mills on the coast, producing bullion at the rate of about \$1,000 or \$1,200 per day, with room to add ten more stamps, if necessary, which will undoubtedly be the case, should the Paradise mine continue as rich in the future as it has been in the past. The machinery is all working splendidly, and the mill is being run to its full capacity, day and night. There is enough ore on hand and at the mine to keep the ten stamps in constant operation for six months, and it is the intention of the company to run the mill and mine for all they are worth the coming fall and winter.

SOUTH MOUNTAIN DISTRICT.

A PROSPEROUS CAMP.—The *Silver State*, published at Winnemucca, Nevada, with reference to this district, informs us that Thomas J. Taylor, an experienced miner and smelter, who went from Eureka to South Mountain to examine the mines of that section, and, if favorably impressed with their appearance, to start a smelting furnace to reduce the ore, arrived here yesterday on his way home. He is of the opinion that the mines are rich and permanent, and that South Mountain is destined to be a great producer of base bullion. A furnace is successfully running on ore from the Mono, and he thinks there is ore enough to keep it running until a tunnel, which is now being run, cuts the ledge, after which he thinks there will be no trouble in getting plenty of ore. The first shipment of bullion was made from the furnace Saturday. In consideration of 10 tons, which assays \$668 in silver to the ton. Another shipment will be made this week, and, as the furnace is running splendidly, it is expected that shipments will be made regularly henceforth. Mr. Taylor believes that South Mountain is destined to be a lively camp, and that it will be one of the greatest base bullion producing districts on the coast.

SPRING VALLEY DISTRICT.

EAGLE MINE.—*Silver State*: This mine has been incorporated as the Vandewater G. & S. M. Co. It is located in Humboldt county, 13 miles from the C. P. R. R. The company owns altogether 14 well-defined ledges, all prospecting sufficiently to determine their value. In addition to these ledges, it owns a water right which is very valuable, and which is expected to yield a profit of \$50,000 or more per year from the sale of water. The company owns a 15-stamp mill, and all the outbuildings and other appurtenances of a first-class and well equipped mine. Within six miles of the mill is a salt marsh, from which all the salt needed is obtained at the cost of hauling only. There are several hundred Chinamen washing gold in the canyon, which divides the property into two companies. The Chinamen have, during the last five years, taken out over \$1,300,000 in gold—not placer gold, but fresh quartz gold—which establishes the fact that the gold of the canyons has but recently been washed from the hills on either side of the canyon, and must have come from the different ledges owned by the Vandewater company. There is sufficient ore exposed in the company's mines to last for 25 years, with 25 stamps, and it is to be added for five years, such ore yielding \$80 per ton, and the cost of milling being less than \$7 per ton. A new vein parallel to the Eagle has been discovered within the last fortnight, very wide and well defined and very rich. This new discovery is what is known as a blind ledge.

PIOCHE DISTRICT.

DAY MINE.—*Record*, Oct. 13: The last official letter of A. S. Gould, Sup't, says: "Our work of sinking in the ore body from the lower tunnel level is being driven with all possible energy. We meet with some spar boulders, but the ore continues strong, and of about the same character as our last report. We find streaks and channels of a very dark, black, soft, earthy material, which assays \$172.79. Our average assays from the sides and bottom of ore shaft is \$125.58."

HILLSIDE MINE.—Forty-five tons of ore are daily shipped down to the furnace, which started up the fore part of this week and is doing good work, turning out a large amount of bullion.

RAYMOND & ELK.—Mr. Mill, Sup't, says: "The ore on the 11th is improving as we work up in the drift we are all in good ore; we have been raising from 11th to 10th and expect soon to make a connection; we are running a cross-cut to make a connection with upraise from 11th and expect to get into a body of ore which may prove to be a different vein than we ever had. We are sinking a winze on the 1000-ft level in a body of low grade ore, and expect to take out a large quantity of ore at this place. Samples from top of upraise go from \$100 to \$150. Prospects, as we go up, seem to look more favorable."

WILLOW CREEK DISTRICT.

FLACON MINES.—*Silver State*, Oct. 13: H. H. McCollie informs us that the Chinese who are placer mining on Willow Creek, are doing well, considering the scarcity of water. They do not average over three hours' work day, yet they make what Chinese call "good wages." Mr. McCollie brought down 14 ounces of gold dust, taken out by the Chinese, and sent it to the mint to be assayed.

ARIZONA.

GLOBE DISTRICT.—News from this district in the *Silver Belt* report that ore worked in the Isabella mine gave \$955 per ton. The Mexican mine now has a well-timbered working shaft 70 ft deep. The shaft is not on the vein, and ore body not yet reached. Cox & Coplin are now drifting from their deep shaft towards the main vein and at the same time taking out rich ore. The vein is strong and looks well for a continuance. They are putting up commodious winter quarters.

HEACHUCA.—The Tombstone *Nugget* says: "There are now three live camps in the mountains, one at Hartford, one at Ash canyon, and one at the south part of the mountains, with probabilities of some more. Recent discoveries of new veins are creating much interest, and some excitement. Some of these new discoveries are said to be 30 ft wide of cropping, and a mile in length, at any point of which rich ore can be found. Some of these are in a gangue of quartz, with indications of its being a vein of free-milling rock, and others of being rich lead ores for smelting. None of them have as yet been developed enough to disclose their true class and character, but enough is shown to prove them to be fissures cutting the formation in their strike. Work is progressing and assays are being made. Andy Baldridge is in town from Mulo mountains, where he has discovered some new mines. Assays made by A. J. Mitchell show the ore to be worth \$238 per ton. Andy claims that he has a lead which contains 40 ft in width of better ore than the sample he had assayed. The claims lie to the east of the Mule Pass and are entirely new to prospectors."

COLORADO.

CENTRAL CITY.—*Register-Call*, Oct. 17: Rich gold discoveries have been made in the Big Horn mountains, about 25 miles northwest of Fort McKinney.

IREM.—The Georgetown *Miner* publishes a private letter from Battle Mountain, on Eagle river, which says a number of rich strikes have been made in that locality, in one claim 25 ft of mineral having been uncovered. The sample can be seen cropping out all along the face of the mountain. The formation is lime, porphyry, iron and quartzite, exactly the same as at Leadville.

IDAHO DISTRICT.—The *Iris* says that in regard to the

Idaho tunnel, since the first lode was cut, at a distance of 48 ft from the mouth of the tunnel, successive lodes have been found at every 25 ft, the last lode cut showing a strong mineral vein six ft in width, carrying sulphurets assaying three ounces in gold and 118 ounces in silver, and a narrow vein of gray copper on the hanging wall assaying half an ounce in gold and 510 ounces in silver. The last lode discovered in the Idaho tunnel, called the Beta, bids fair to prove a bonanza of itself, and the entire enterprise in its great value is fully established. The Hub mine has been taken possession of the past week by E. E. Mack, and a force of men put at work in the shaft and the different drifts, and mineral of a high grade being brought out in large quantities. Shifts have also been placed in the adit already started, which is to cut the shaft at a depth of 150 ft. Another adit is being started in Boomerang gulch which will cut the shaft at a depth of about 400 ft. The town of Idaho Springs is becoming a permanent mining camp.

IDAHO.

SNAKE RIVER PLACERS.—*Enterprise*, Oct. 16: While at Blackfoot City a few days ago we paid a visit to the placer diggings of Lawrence & Holmes, some two miles or so southwest of town. They are running two sets of plates, silver-plated and manufactured by the Gorham Manufacturing Company of Connecticut. They have taken out a ditch from Blackfoot creek which supplies them with plenty of water for running a dozen plates more than they have. From this main stream they have lateral ditches running over to the bank of Snake river where they have the plates set. Water is turned on through these lateral ditches, which wash the dirt, sand and gravel through a flume and over a sieve which carries off the coarser material while the gold and finer sands wash through on to the plates, the gold adhering to the plates and the sand and dirt washing away. Mr. Holmes cleaned up from the two plates while we were there about 10 ounces of amalgam, valued at about \$0 per ounce, as the proceeds of one day's run. This is done with the labor of two men we believe, so that they can say truthfully they are making from \$25 to \$30 per day to the hand. With improved facilities they can increase upon the quantity of gold saved. The gold is of the flour gold variety, very excellent quality and no end to the quantity of it.

ADVANCE IN IRON.—Although we are not producers on this coast of such articles as iron pipe, sheet iron, nails and other articles of the same class, and the prices in this market are controlled by those at the Eastern manufactories, yet we may regard the late advance in the price as an evidence of prosperity, which is returning to the country in general, and is making itself felt on this coast. Messrs. W. W. Montague & Co., of San Francisco, in a letter, speaking of the matter, say: "In the early part of July the first signs of an advance in the iron market were visible. No great advance took place until the latter part of August. The first week of July pig iron was selling in New York at \$18.50 to \$19 per ton for foundry, and to-day it is difficult to obtain the same grade of iron at \$30, an advance of 55%, with a prospect of its reaching \$35. Never before in the history of the iron trade of the United States has the advance been so sudden, so rapid and so great in such a short time. The question asked: 'What has caused this enhancement of values?' Demand, which is far in excess of supply. What has created such a demand? General prosperity in business. After six years of the most extreme commercial depression throughout the country, the United States may be said to have fairly entered upon a new era of prosperity."

PRECIOUS METALS IN CANADA.—The *Montreal Witness* says that a few years ago Gen'l Baker, then Surveyor-General of Minnesota, explored the region round Northern Light lake, north shore of Lake Superior, and became convinced of its richness in gold and silver. Afterwards he formed a company, which has had 16 experienced miners at work all summer uncovering veins of mineral. On the Canadian side, near Arrow lake, vein-matter about 30 feet wide was uncovered, and through this run four seams of rich mineral, one, 1 foot wide, two, 2 feet wide, and a fourth, 15 inches wide; one of the 2 feet mineral-bearing seams at a depth of 14 feet, showing a width of 5 feet, while the miners are fully satisfied that the mineral seams all come together at a depth of 50 feet. The seam in which the shaft was sunk already shows masses of mineral that are simply incredible for the depth reached—only 14 feet. The ore is of that species known as gray copper, and carries both gold and silver. It was assayed by Prof. Peckham, of the Minnesota State University, and showed \$49 in gold and \$57 in silver per ton. One of the best indications is that the ore is evenly diffused throughout the whole mineral matrix. The new mining district is 300 miles southeast of Emerson, and 50 miles due north of Grand Marais, a Minnesota harbor on the north shore of Lake Superior.

The visiting Governors at Philadelphia visited the old Christ church Sunday, which Washington attended while President.

UNEASINESS is expressed at New York for the safety of vessels exposed to the hurricane on the Atlantic on the 10th inst.

The restrictions against newspaper correspondents accompanying the British army in Afghanistan have been withdrawn.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

COAST RANGE M. Co.—Object, to operate in Marin county. Capital stock, \$100,000. Directors, Edgar Briggs, A. Peck, F. W. Bowen, George T. Emery and E. A. Peck.

SAN RAFAEL M. Co.—With like objects, capital stock and Directors.

THE "SUN" PUBLISHING Co.—Capital stock, \$10,000. Directors, Oscar W. Dunbar, J. H. Delahanty, John Freck, Edward C. Ellinghouse, James A. Cowles, Frank T. Jordan and Daniel Connell.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

[FOR THE WEEK ENDING OCT. 14TH, 1879.]

220,522.—DRAIN AND OTHER PIPES.—John P. Culver, S. F. 220,527.—Yeast Compound.—J. H. Goll and A. Späner, San Francisco.

220,536.—FORMATION AND BENDING OF POTTERY PIPES.—Wm. B. Hyde, Oakland, Cal. 220,630.—DUMPING WAGON.—A. McFarlane, San Bernardino, Cal.

220,542.—IMPLEMENT FOR GRAPPLING, WITHDRAWING AND PERFORATING PIPES AND TUBES IN ARTESIAN WELLS.—B. F. Mull, Merced, Cal.

220,656.—GOLD WASHER.—Wm. H. Pilliner, Elko, Nev. 220,553.—GAS CHECK FOR WASTE AND SEWER PIPE.—Wm. Wilson, Oakland, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC GRIP FOR ROPE-RAILWAYS.—Henry S. Grace, S. F. No. 220,233. Dated Oct. 7th, 1879. This invention relates to an improved apparatus for connecting a car with the continually-moving rope or cable by which it is to be driven; and it consists in the combination of two gripping devices connected with each other and with a mechanism within the car to be propelled, so that when one grip is released, the other, which follows or is behind this first one, will be caused to take hold, and vice versa—the object being to enable one cable-road to cross another one without entirely disconnecting the car from the cable which drives it. This device also enables the cars to be used with a cable which turns a corner, as the grips are easily detached and the momentum will carry the car around the corner, where it again meets the cable and connects with it.

WATER WHEEL.—David H. Anderson, S. F. No. 220,212. Dated Oct. 7th, 1879. This invention relates to an improvement in that class of water wheels known as "hurdy-gurdy" wheels, which are driven by the momentum of the water, and in which the water is received into the buckets from the outside and discharged in the same manner. It consists in so mounting the buckets or floats on the flanges or rim of the wheel that a continuous span is left between the inner edges of the buckets and periphery of the wheel, so that the momentum of the water is not lost on the first bucket, but is distributed over a number, until its moving force is entirely lost, when it leaves this wheel.

ROTARY ENGINE.—B. E. Letang, San Leandro, Cal. No. 220,246. Dated Oct. 7th, 1879. This invention relates to an improved rotary engine, and consists in attaching to a shaft a series of peculiarly-shaped pistons arranged in a circle on the shaft so as to rotate it, as steam is applied to one side of said pistons. This engine is very compact and light, occupying very small space and requiring less steam than reciprocating engines. As the steam acts on three or more of the pistons at one time, all on one side of the shaft, great power is obtained and direct rotary motion imparted to the shaft.

COMBINED STEAM HARVESTER AND THRESHER.—Wm. H. Foye, S. F. No. 220,366. Dated Oct. 7th, 1879. This invention relates to an improved apparatus for harvesting grain, and it consists in a novel combination of a mechanism for cutting and heading the standing grain, suitable carrying and elevating helts, and a threshing and cleaning machine, all mounted upon a frame-work having hearing wheels, together with a novel steering device and devices for raising and lowering the front and rear and the ends of the reaper. In combination with these devices, an engine is employed to drive the sickle and thrasher, so that, while the machine is drawn over the field by horses, the reaper and thrasher are driven by this engine at any speed required, and independently of the movement of the machine over the ground, thus cutting thick or thin grain with equal facility and relieving the team, as the tractional force necessary to drive the machine is avoided.

STEAM FARMING APPARATUS.—Wm. H. Foye, S. F. No. 220,365. Dated Oct. 7th, 1879. This invention relates to certain improvements in engines and apparatus for farm work, the apparatus being interchangeable, so that portions of it may be employed with the engine during the plowing season, while other portions may be employed with the same engine during the harvesting season, by simply removing the plowing apparatus and substituting therefor that necessary for harvesting, so that the whole will form a comparatively cheap and economical "plant" for all the principal work of a farm.

DOUBLE-ACTING REVERSIBLE GANG PLOW.—Wm. H. Foye, S. F. No. 220,367. Dated Oct. 7th, 1879. This invention relates to certain improvements in gang plows of that class which are hauled across the field to be plowed

by means of engines placed at one or both sides of the field with suitable anchors and connecting and operating ropes; and it consists in mounting two gang plows upon a frame in lines which cross each other diagonally within the frame, one gang extending so as to plow in one direction while the other gang is mounted so that it will plow in the opposite direction. These two oppositely acting gangs of plows are provided with mechanism by which one or both of them may be raised from the ground, and this frame is mounted upon a series of adjustable hearing wheels, three of which travel all the time upon solid ground.

SAFETY DEVICE FOR ELEVATORS.—James H. Culver, S. F. No. 220,222. Dated Oct. 7th, 1879. This invention relates to an improved safety device for elevators, and it consists in constructing at the bottom of the elevator well a box provided with flaring slots in its mouth, into which the elevator may fall in case the rope breaks or unwinds and the ordinary safety clutches do not act. This box has suitable discharge openings for the air to pass out gradually when the elevator or cage drops into it, and the partially confined air acts as a cushion into which the cage falls, so that its speed is gradually checked and no harm results to the occupants of the cage. Springs are also placed in the bottom of the box, which will also tend to lessen the force of a fall.

MACHINE FOR SEAMING CANS.—R. D. Hume, S. F. No. 220,239. Dated Oct. 7th, 1879. This invention relates to certain improvements in machines for the construction of the containing-cans for hermetically-sealed goods; and it consists in making the crimping-machine adjustable to crimp cans of varying sizes.

Education of Youth.

The Virginia *Enterprise*, speaking of the boys of Virginia City, advances some ideas which with certain qualifications are generally applicable to American boys. It says: "They are strong race physically and mentally, and they are bright even to precocity. Disciplined and placed in worthy paths and their lives would be real ornaments, but as they are drifting, when manhood turns on its head of steam there will surely be a wrecking of trains. With this greatest mine on earth under our city's streets, no boys can learn mining even if they have lived all their lives here; with this most magnificent mining machinery on earth, at work upon our mines, no boys can learn to be mechanics, and the same rule attaches to all other occupations."

This problem of technical education is involved in this matter, and if it is to be solved at all it will be brought about by the strenuous efforts now being made in this country and in Europe. There is a greater demand for skilled labor than for unskilled, this may be considered the cardinal point of this question, and it is pretty well demonstrated from the fact that skilled labor is very seldom obliged to go a-hogging for employment. In nearly every department of mechanics and mining there exists such a division of labor that apprentice work as it is used to be known is at a minimum. We may be mistaken, but we certainly have reason to believe, from every-day experience, that purely physical labor remains chained to the dreary routine of "horse work," without very many opportunities to rise above it. This old system of learning to be a machinist by scraping castings, or the shoemaker's art by sawing wood for several years, is very much modified by the quantity of intelligence and skill employed by the new band. The lad who has received a good technical education need not now fear to be hegin at the lowest rung of the ladder, for his merits will not permit him to remain there long.

If his boys of Virginia City were offered the privilege of a technical and experimental school in the mining business, we believe many of them would rise to his honor to the community. Some unknown and undeveloped genius would be brought out, which is now being smothered through lack of opportunities. Boys live an artificial life in cities because they are crowded out of avenue of progressive development on the ground of inexperience. It will not do to get rid of them by sending them away, for the evils complained of by the *Enterprise* would be perpetuated, not cured. If the boys are not proficient and are inexperienced, how can they be expected to become proficient or experienced unless they are taught? We have no right to complain of the evil future in store for our boys when we have the shaping of that future, and are in a measure responsible for it by failing to afford them the educational advantages which they have the right to expect from us, and with which it is our moral and legal duty to provide them. If the next generation is worse than the present, it is correct to say that the present is responsible for it. If the boys of Virginia City use such infamous language that even "old roughs" turn away with a shudder, they are only following the instructions of "old roughs," who are permitted to demoralize them. The educational problem is easy of solution, if begun properly.

PAUL BRYTON, the swimmer, is coming to California to give exhibitions.

News in Brief.

THREE Afghan Chiefs are imprisoned at Cabul. FRENCH agriculturists are emigrating to Texas. THE Marquis of Lorne will visit England about Christmas. THE Chinese Spanish embassy left New York Thursday for Cuba. RICHARD CLIFFORD, District Attorney of Trinity county, is dead. THE Albanians are determined to resist the cession of Epirus to Greece. STEAMSHIP *Periere* from Havro brought \$1,843,000 to New York on 21st. KING ALFONSO'S marriage will take place on the 27th or 28th of November. The recent floods in Spain were terribly destructive of life and property. A DENSE smoke on the St. Lawrence river has entirely suspended navigation. It is reported that the Russians have occupied Merv after several engagements. INSURRECTIONARY movements are reported in Chihuahua and Durango, Mexico. It is rumored in Constantinople that a crisis impends in the Turkish Ministry. An amnestied Communist is a candidate for a seat in the Municipal Council at Lyons. On railways within 30 minutes of New York drinking water is being sold by the glass. A DISTURBANCE recently occurred at Lebanon, Syria, in which several persons were killed. A PACKAGE of papers thrown from the balloon Pathfinder has just been found at Lake, Ind. SILVER in London, 524d; consols, 97 11-16; 5% United States bonds, 105½; 4s, 105½; 4½s, 109½. At Liverpool wheat is quoted at 11/12s for average California white, and 11s 10d at 12s 6d for club. THE severe snowstorm of Friday extended throughout Galicia, Russia and the Alpine regions. THE region around Milledgeville, Ga., is under the reign of a gang of murderers and incendiaries. THE death at Orange, N. J., of Rev. Wm. R. Whiting Hall, Episcopal Bishop of Maryland, is announced. SNOW fell heavily in Austria October 21st, covering the ground in some places to a depth of several feet. ALEKO PASHA, Governor of Eastern Romenia, declines to visit Constantinople on the invitation of the Sultan. In the recent flood in Spain 3,500 houses and 120 mills were destroyed, causing a damage of 60,000,000 francs. THE value of the exports of animals from the United States increased from \$389,618 in 1878 to \$3,379,200 in 1879. AN anti-ment meeting was held Sunday at Newport, Mayo county, Ireland, at which 5,000 persons were present. NOVEL USE OF ETHER.—A prisoner, named Uhlmann, recently barricaded himself in his cell at Vevey, Switzerland, and defied the gendarmes to take him before the judges. It was not thought advisable to shoot him, and the court would not wait till he was starved into surrender, so ether was thrown into the cell until he became sufficiently stupefied to be harmless.

Scientific Press Supplement.

A MONTHLY BULLETIN OF PACIFIC COAST SCIENTIFIC REPORTS, RESEARCHES, ETC.

The aim of the publication is to gather and present in a convenient and durable form all the valuable scientific matter practicable, in a publication specially representing scientific development in this comparatively new and rich field of observation and discovery.

It forms a select medium through which all scientific writers on the coast may co-operate in publishing their thoughts and investigations to the scientific world in a befitting dress and manner.

It is well printed on good paper and furnished at the reasonable price of \$1.50 per annum, postage paid. Single Nos., 10 cents. [Copies for extra circulation can be ordered in advance for \$5 per 100.]

It is issued in the early part of each month. Each number will contain eight or more pages. The editors and publishers will aim to make such a publication as the scientific and progressive men of this coast will support cheerfully and take pleasure in sending to their friends and correspondents in all parts of the civilized world.

The SUPPLEMENT is an independent publication, and will not be mailed to subscribers of the "Mining and Scientific Press" unless paid for as a separate subscription.

DEWEY & CO., PUBLISHERS, Office Mining and Scientific Press, No. 202 Sansome Street, San Francisco.

A Library for Inventors.

We have at our patent offices, No. 202 Sansome street corner Pine, a complete set of Patent Office reports, containing engravings and claims of EVERY PATENT ever issued in the United States.

We have also a complete set of the MONTHLY VOLUMES issued by the Department, with full detailed description and large drawings of all the patents issued since the time when these volumes were first published.

A set of all the LAW BOOKS ON PATENTS is also on our shelves ready for reference. We have also the British Commissioners reports, Canadian Patent Office reports for all British North America, full files of MINING AND SCIENTIFIC PRESS, PACIFIC RURAL PRESS, Scientific American, Scientific American supplement, American Artisan and other American and foreign scientific and mechanical journals, as well as mechanical dictionaries, chemistries, encyclopedias, and other works of reference.

Inventors and patentees are WELCOME TO EXAMINE at their leisure any of the books in the above sets, and we shall be glad to give them any assistance in hunting up what they want.

Our library is the most complete of its kind on the Pacific Coast in every respect, and we are continually adding to it as occasion demands. DEWEY & CO., Patent Agents and Publishers, No. 202 Sansome street, corner Pine, San Francisco.

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	2 Complete volumes, 1st half (of year).
1870	20	2 Copies of No. 2, Jan. 1st.
1870	20	1 Copy each of No. 1, Jan 1st, 3 of Jan. 14th, 7 Feb. 11th, 6 Feb. 4th.
1870	21	1 Copy of No. 7, August 13th.
1871	22	5 Copies of No. 1, Jan. 7th.
1871	22	3 Copies of No. 5, Feb. 4th.
1871	22	1 Copy of No. 3, Jan. 21st, 6 of Feb. 2d, and 1 of May 1st.
1871	23	1 Copy of No. 2, July 15th, and 9 Sept. 2d.
1872	24	2 Copies of No. 4, Jan. 27th.
1872	24	3 Copies of No. 7, Feb. 17th.
1872	24	2 Copies of No. 17, April 27th.
1872	25	1 Copy of No. 10.
1872	25	1 Complete volume, last half (of year).
1873	26	3 Copies of No. 8, Feb. 22d.
1873	26	3 Copies of No. 9, March 1st.
1873	26	2 Copies of No. 10, March 8th.
1873	26	1 Copy of No. 7, Feb. 15th.
1873	27	3 Copies of No. 20, Nov. 15th.
1873	27	4 Copies of No. 21, Nov. 22d.
1873	27	3 Copies of No. 24, Dec. 13th.
1875	30	1 Copy of No. 4, Jan. 23rd.
1875	30	1 Copy of No. 5, Jan. 30th.
1875	30	1 Copy of No. 8, Feb. 20th.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send one but worthy men.

J. L. THARP—San Francisco.
B. W. CROWLEY—California.
A. C. KNOX—Pacific Coast.
S. V. BLAIR—California.
G. W. McGRATH—Santa Clara county.
MILTON KENNEDY—Kern and Inyo counties.
J. B. BACHLEDER—Shasta County, Cal.
H. H. MESSENGER—Arizona.
THOS. H. MANNING—Nevada, Idaho and Montana Ter.
CAPT. W. H. SEAMENS—Arizona.

FRESH attractions are constantly added to Woodward's Gardens, and among which is Prof. Gruber's great auditor, the Zoögraphicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How to STOP THIS PAPER.—It is not a burlesque task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Books for Miners and Millmen

KUSTEL'S RECASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated. 142 pages. 1870. A valuable and carefully written work. Postpaid, \$2.50. Published and sold by Dewey & Co., S. F.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 472 pages and 83 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Post-paid, \$10.50. Sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated. 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable to miners' use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Post-paid, \$1.00. Sold by Dewey & Co., S. F.

PALACE RESTAURANT

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

This best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, - - - PROPRIETOR.

SANDERSON BROS. & CO'S

BEST REFINED CAST-STEEL.

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock, and for sale at

21 and 23 Fremont Street, S. F., - H. D. Morris, Agent.

Trall Hygienic, Medical and Surgical Sanitarium.

No. 8 Ellis Street, San Francisco, Cal.

Treatment by a Purely Scientific and Rational Method Without Drugs of any Kind.

THE TREATMENT DEPARTMENT EMPRACES ALL APPROVED REMEDIAL AGENTS, AS OXYGEN INHALATIONS, VACUUM TREATMENT, THERMO-ELECTRIC, TURCO-AMERICAN, ELECTRO-MAGNETIC, GALVANO-CHEMICAL, STEAM, VAPOR, WARM AIR, AND ALL FORMS OF WATER BATHS;

Swedish Movements, The Health Lift, Spirometer or Lung Strengtheners, Steam Atomizers, all Electric, Galvanic and Surgical Appliances, Sun Baths, and Solar Ray Surgery, new and perfect Truss for the Radical Cure of Hernia, lately discovered Chemical Compound for the speedy, safe, painless and permanent removal of Cancer, Scientific and successful method for the Cure of Piles, etc., etc.

Let Aime to keep Abreast with, if not in Advance of the Progressive Age.

It has been the mission of this System to mold public sentiment and this Institution will hope to be no disgrace to the immortal name it has assumed. The time has come when Physicians of this School can afford financially to keep a conscience; in fact it is disastrous financially as well as morally to compromise the truth one iota; hence patients can rest assured that they will be treated by the Physicians after the most approved and scientific methods, out of pure and enlightened selfishness, recognizing the truth and beauty of this great principle:

The Universe is so ordered and arranged that the real and permanent good of every creature is best subserved in promoting the real and permanent good of every other being.

THE BOARDING DEPARTMENT.

The table will be supplied with the best the excelsior market of the world affords, embracing fruits, grains, vegetables, meats, fish, fowl, eggs, cream, etc. Regular and transient boarders will be accommodated as well as patients. Business and professional men and women who are tired of restaurant fare, may appreciate eating to live a more healthful and enjoyable life. Pure food means pure blood. Pure blood means good health.

The vegetarian dishes have demonstrated beyond the possibility of a doubt that farinaceous dishes, sweet milk and fruit, are sufficient to maintain a hard working man in perfect health. Such a diet might certainly be substituted by sedentary people for their greasy steaks and ragouts.—*Popular Science Monthly, December, 1878.*

The Rooms are pleasant, warm, well ventilated and sunny; convenient to treatment rooms, so as to afford the best advantage of nursing and professional attendance.

GENERAL PRACTICE.

Fever, and in fact all cases may be treated at home successfully. Patriotic commitment cases are taken in the Institution or attended at home in any part of the city or country. Preparatory treatment in these cases is most important.

Testimonials of extraordinary cases and cures can be seen on application. The most desperate cases, and especially those that have been given up as incurable by the old methods, are invited. Puerperal and typhoid fever and diphtheria cases, after all other methods have failed, may be said to be a specialty. *Send for the TRALL HEALTH JOURNAL.*

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

STEEL CASTINGS.

From 1-4 to 10,000 lbs. Weight.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address

Chester Steel Castings Co.

Works, Chester, Pennsylvania. 407 Library St., Philadelphia

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no hack or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Amusements.

VOLUME XXXIX
Number 18.

Prof. Church on the Comstock Lode.

Two years ago the United States Government determined to resume the task of surveying the Comstock mines, which it had carried up to the year 1870 and then abandoned. The first intelligent study of these important sources of bullion was made by the celebrated Austrian geologist, Von Richthofen, about the year 1864. Mr. Clarence King followed him in 1869, and eight years later Prof. John A. Church was employed to take up the long neglected work. He spent five months in constant examination of the mines; and the results of his work are now published by Messrs. John Wiley & Sons, of New York. He was attached to that department of the Government service which is known as the Surveys west of the 100th meridian, the scope of which has now been reduced, the scientific work being taken from it and placed, with that of all other Government surveys, in the hands of a special scientific commission, under the charge of Mr. King. The Government, therefore, will not issue any further report from Prof. Church, the present volume,* published by a business firm, being an enlargement of the report written for the Government.

Before entering upon a discussion of the hook, it may be well to remark that Prof. Church's appointment was the first break in a long series of years, during which the interests of the mines were wholly neglected, though almost everything that had no relation to the welfare of the Western country was carefully hunted up and described. The first step in the new direction was made by the Chief of the Surveys west of the 100th meridian, and the first result of the new departure is Prof. Church's hook. The number of new facts which he has collected and new explanations which he has found, is an evidence of the room there is in this important field.

Another proof is the remarkable interest which has been shown at home and in Europe in the preliminary report made by him a year ago. That undertook to explain the cause of the heat in the Comstock mines by the new theory of kaolinization. It has been repeatedly translated and published in Europe, and has formed the subject of comment by authorities in mineral studies.

The present volume is quite as original. It undertakes to give the history of the Comstock lode, as it is shown in the structure and position of the quartz bodies and the country rock.

Probably no other assertion made in the hook will be considered so startling and, perhaps, combatted so much, as the assertion that the lode is not a true fissure vein. That is to say, Prof. Church says that there was not a great crevice into which the ore penetrated, and in proof of this he points to the absence of an east wall, the enormous thickness of some quartz bodies—200 feet in the Con. Virginia and 300 feet in the Jacket—and the fact that there is no such thing as vein matter outside of the quartz bodies. Above and below them we find nothing but country rock, and no sign of a vein. He considers it impossible for a crevice to open wide enough to take in a body 300 feet thick and yet show no evidence of its continuation, above it or below it.

We are inclined to the belief that the theory which the author offers to take the place of the fissure-vein origin of the Comstock, is one that promises just as great permanence in depth as if there were a fissure. He attributes the ore to waters which ascended from a great depth, which, he thinks, may be as much as 12,000 feet—at all events, much beyond the possibilities of mining. Before giving Prof. Church's theory, we will recount some of the facts upon which he based it.

First, as to the position of the quartz bodies. It has always been noticed by miners that there was some connection between the position of ore and the ravines of the surface; but geolo-

gists are not ready to acknowledge that the form of the surface, which is a carving made by rain and frost, can have anything to do with the deposition of ore in the crust away from these agencies. But Prof. Church finds that the observation of the miners is true, and that the position of the quartz and the sculpture of the surface are governed by a cause that preceded them both.

The black dyke forms the west wall of the lode, and this wall shows a series of undulations, which would make low hills and shallow valleys if it were laid on its broad side. The quartz invariably forms on the shoulder of these hills. Sometimes it reaches clear over the crest, and frequently it covers a large part of the folds; but the author considers that the shoulder of the ridge was the principal point of deposition.

He finds that all quartz bodies, whether they carry ore or not, are curved at one end. They have the shape of a boomerang, the handle representing the long, thin mass of quartz that lies on the top of the undulations, the swell toward the head representing the thickened part of the quartz just at the shoulder of the fold, the

rocks. We believe that in making this observation he is the first scientific man who has attempted to point out the actual channel by which ores have been brought into the positions where they are found. Hitherto, cracks, crevices and fissures have been vaguely spoken of as probably existing even where they could not be found. Indeed, the whole theory of true fissure veins rests partly upon the assumption that a fissure is necessary as a channel to account for the presence of the ore. One advantage of this explanation is that it gives a reason for the frequent occurrence of metallic ores near eruptive dykes, though they are not found or are comparatively rare in the neighborhood of the innumerable faults which are discovered in many localities. Great numbers of such faults are known, but when they are not accompanied by eruptive dykes they do not show the intimate relation with metalliferous deposition which is recognized as a peculiarity of igneous rocks.

Entering the rocks by this sheath of broken material next the dyke, the waters would deposit their load of quartz in any crevices adjoining; and now we reach the significant fact that

SUBSTITUTED MASSES IN MINERAL VEINS

strong curve comes then, following the west wall and carrying the quartz into one of the valleys. Sometimes the curve is at the north end, sometimes at the south end, and in the Justice the ore channel, near the surface, ran N. E.—S. W. From this diversity the author concludes that magnetic causes had nothing to do with the formation of the quartz.

It is well known that the rocks of the Comstock country are diorite, porphyry, andesite and trachyte, which appeared in the order given. Prof. Church says that the andesite did not come on the ground until the diorite and porphyry had been deposited in broad sheets of rock, folded and then raised up to about their present inclination. The folds now form those hills and valleys in the west wall which we have just spoken of. The rocks were thoroughly cool when the andesite penetrated them, and as that came up in a melted condition, it baked the rocks for a few feet on each side. This is a common thing at eruptive dykes, which are very often bounded on each side by a mass of rock which has been shattered and fissured by their heat, and often several feet thick. Water can penetrate such a seam with great ease. The black dyke has just such a shattered seam of porphyry next it, and Prof. Church says that this was the channel by which the metal-bearing waters entered the

the principal deposition was on the shoulder of the folds or ridges. This indicates crevices there, and to account for their presence Prof. Church offers an elaborate explanation. He says that the rocks of the Comstock are stratified even when their origin is eruptive, and that in folding the different layers formed concentric arches, just as they do in all stratified rocks. After they were folded a new eruption occurred, and an immense mass of andesite was poured out on the surface. The weight of this new rock flattened the folds and squeezed out the layers of which they were composed. Any one of these is of greater length in the crest of a fold than the one under it, and when pressed out it would arch itself slightly over its neighbor just at the edge of the crest, where there would be some relief from the weight of the andesite. This arching might be very small indeed, and form no more than the merest parting of the strata, but such partings are quite enough to admit the waters.

The reason why the ore is on the edge of the valleys is now apparent, and the explanation also accounts for the similar valleys on the surface. These surface depressions are not the product of erosion merely. They mark the site of troughs which were produced by the original folding, and to these troughs the old surface waters naturally took their way, widening and

deepening them. In this way we see that the position of the ore in the depths of the crust and the form of the surface may have an intimate connection, in some kinds of mineral deposits, because the position of the two is determined by a common cause. This explanation is quite as novel as that relating to the ore channel, for so long as the existence of great fractures was felt to be necessary to the formation of ore bodies like those of the Comstock, it was impossible to imagine how there could be any relation whatever between the form of these cracks produced by rending of forces of great power, and the form of the surface which is mostly the product of atmospheric action.

This is one of the evidences that the Comstock is not a true fissure vein, for the fact of a connection of some kind between the interior deposits and the exterior sculpture has long been acknowledged by those who are familiar with the development of the lode. In the place of fracture, Prof. Church puts the ordinary dynamical forces, which have molded the rocks in every part of the earth.

But this explanation supposes that the crevices opened between the strata were very small, and Prof. Church says they may have been too narrow to admit the hand. How then have the vast ore bodies been formed? This is accounted for by the process of substitution. When water is filtered through powdered feldspar the rock is decomposed and clay is formed. Heat and pressure greatly increase the action, and the author holds that when the crevices between the strata were filled with hot siliceous water, the rock layers were eaten away and taken into solution, or carried off in a very fine condition and discharged at the surface. Quartz was substituted for the solid rock, and as each layer would be attacked on both sides, the several seams of quartz would finally unite and produce a great body.

The mines give proof that this was the origin of the quartz. Every one knows of the horses that the lode contains, and Prof. Church says that these horses are the remains of porphyry layers that have been only partly removed. In the center of the quartz, whether barren or not, the deposit may be almost or entirely composed of silica, but toward its edges it is invariably broken up into alternate layers of silica and porphyry. That is because the edges of the deposits were not reached by the waters as early as the center, and the horses represent a part of the lode that was under the action of the water for only a portion of the time. Though this explanation is new, the market long ago discovered that a horse in a Comstock ore body meant the approaching termination of ore. The edges of the quartz bodies interleave with the porphyry layers, and the appearance of these layers indicates that the boundaries of the deposit are near. Prof. Church says, that the existing definitions of vein structure do not satisfy the conditions of the Comstock. What those definitions are, can be seen from the PRESS of October 4, 1879, where they are given by Mr. Phillips. To the various kinds of veins there described, our author proposes to add *Substituted Masses*, which, he says, have the deep origin of true fissure veins, and yet are not formed in a great crevice.

This mode of formation is illustrated in the following figure copied from the hook. It shows how the layers of porphyry may be pressed open by a weight laid on them, and how the union of the little crevices between them by the removal of the rock would form just such a lens of quartz as we find in the Comstock.

But all that we have so far discussed is of small importance compared to the discovery of the true vertical position of the ore bodies. The position on the strike is on the shoulder of the curves in the west wall, as already stated, and on the dip the ore is invariably found, says Prof. Church, in the steeper parts of the lode. The flat portions never contain it. But to ascertain what are flat portions the dips compared must be taken from the same locality, for all dips in Gold Hill are less, on the average, than those in the Virginia portion of the lode. Our readers are familiar with the theory so commonly accepted that the ore bodies of the Comstock stand vertically in the lode, or rise from the footwall to the hanging. Prof. Church says that this is not true. They follow the footwall closely, but lie only in the steep parts of

[CONTINUED ON PAGE 231.]

Suggestions for the Land Commission.

EDITORS PRESS:—I enclose a copy of a communication addressed to the Public Land Commission, Washington D. C., which you can publish if you think it worthy of space in your journal.—Geo. W. Jones, Esq., Exchequer Mill, Silver Mountain, Alpine Co., Cal., Oct. 20th, 1879.

To the Public Land Commissioners:—Having devoted the greater part of the past 20 years to prospecting, mining and working various kinds of ores in Colorado, Utah, California, Canada, New Hampshire and the Lake Superior iron and copper regions, I feel competent to answer some of your inquiries appearing in the MINING AND SCIENTIFIC PRESS of the 27th ult.

The first question is answered in the above.

2d. The width allowed by the present law is not sufficient to cover the width of all lodes, in all cases, in all sections of the country. As far as my experience extends to Colorado, outside of Leadville district, the lodes range from three to ten feet in width. My experience there, however, was at an early day; wider formations may have since been discovered. I discovered several veins in Utah that were over 60 feet in width. I opened what is now known as the Jordan in 1870, and exposed a body of ore 60 feet in width. I was defrauded of the property by the workings of the old law regulating mining locations. The old Telegraph mine is a continuation of the same lode to the east. In this county, in Monitor and Silver Mountain districts, it is quite different. Here I find eight formations. Each formation consists of a group of veins or fissures, all having the same course and dip, showing the same outcroppings and producing the same combination of minerals (when developed, as far as explored) peculiar to themselves.

The first and oldest formation produces gold and magnetic iron, the latter (when pulverized and washed) in the form of black sand, running north 14°, dip 32° west. They are on a large scale, ranging from 300 to 2,000 feet in width, the gangue near the surface being pure quartz, stained with oxide of iron.

The second formation consists of a group of ledges ranging from 120 to 150 feet in width, running due north and south, with a dip of 14° west of the vertical line. This formation produces gold and silver of about equal value, copper and lead (in very small quantities), zinc and iron pyrites. The gangue is decomposed white quartz, almost a clay. The "float" from this formation is a peculiar white, honey-comb quartz. The ore is well distributed through the vein, but is richer near the east, or "footwall" side of the ledge.

The third and fourth formations have not as yet, at any point, been sufficiently developed to warrant my expressing an opinion as to their value. They both run north of west and south of east. The former dips to the southwest and the latter to the northeast.

The fifth formation is composed of a group of ledges running magnetic north and south, dipping to the east (magnetic variation here 16° east). They are thoroughly impregnated with iron, but as far as developed, do not yield the precious metals in paying quantities. I would here state that the magnetic needle is not reliable while passing over a ledge of this group.

Ledges of the sixth formation run west 16° north and dip to the north, and produce sulphurets of copper, with frequent specimens of black oxide, except at the point of contact with an older mineralized vein. It then contains the combination of metals belonging to the ledge it is crossing, although it preserves its own stratification and gangue. I attribute this to the precipitating power possessed by the metal belonging to that particular group. The latter veins are 120 feet in width.

The seventh formation bears north 50° east and dips 8° northwest.

The eighth formation bears north 32° east and dips from 10° to 30° southeast.

The last two formations have not had sufficient age to become mineralized. They show prominent outcroppings, as the action of the elements has not had time to decompose and obliterate them. Their width ranges from 10 to 600 feet. As they are quite numerous, they destroy a large portion of the older mineral-bearing ledges, and serve to deceive and mystify the miner by cutting off ore deposits and leading him away from the valuable ledges. I find similar combination of ledges in Colorado and Utah, but as the formations are comparatively narrow, the mineralized ledges are not cut up and displaced to the same extent they are in this section of the country.

In Bingham canyon, Utah, I found several naturally worthless ledges being worked profitably, owing to the fact that the fissure worked out a group of mineral-bearing ledges, enriching the otherwise worthless ledge, producing ore deposits in the form of "chimneys," or "chutes." Prospecting beyond the line of contact with the mineralized veins, the walls and stratification remained perfect, but destitute of mineral.

4th. The courses of all fissures, as well as their width, dip and their comparative age can be readily determined without any outlay of

capital in developing, if proper means are employed to that end.

5th and 6th. Answered in the above.

9th. As previously stated, I have found ledges in this section of the country the width allowed under the present law not being sufficient to cover the full width of the ledge.

10th. I have thus far found that each group of ledges carry their regular course, varying but three or four degrees, allowing for elevations and depressions of surface and the dip of the ledge. If they appear to otherwise curve or present an angle, it is owing to the presence of a later formation which may run nearly the same course; the dip will also probably change, although it may be but slight, and the character of the gangue and combination of minerals will also change.

Having other facts to communicate and fearing my statement may be too lengthy, I will not undertake to answer the balance of your questions at the present time. I will state that I find each and every fissure possessing an electric current of its own, independent of all others. I have been investigating its bearings upon mineral deposits for the past 20 years, and I have given you the results of some of my discoveries. If the laws established by nature were perfectly understood (and it is only a matter of time, as they are as plain and can be as readily comprehended by those who will devote the necessary time and study, as the movements of the planets), there would be no occasion for the numerous litigations that are now hampering this industry, and the money now being expended in developing worthless veins would be employed in working the old mineralized ledges and produce remunerative results.

The "Comstock" was a source of wealth to the country while it was worked in its true dip to the west. When, reaching a later formation dipping to the east, the identity of the old ledge was lost and destroyed, and the later formed ledge was followed in its dip until reaching the crossing of another old and mineralized vein at such an angle as to produce a deposit of ore as found in the lower workings of the California and Con. Virginia claims. When the workings pass below the point of contact, the ledge resumes its naturally barren condition, until, at still greater depth, it may cut another vein of the mineralized group.

The fact that a drift has been run or a diamond drill been sent into the "west country" does not demonstrate the incorrectness of my statements, as I find here fully four-fifths of the ground covered by the first formations, also occupied by later formations, and but few of the latter retaining the wealth of the former at the point of contact. The older formations show no outcropping, but create depressions, as both chemical and magnetic forces decompose the ledge matter, rendering it more sensitive to the action of the elements.

I could give additional facts and information gathered from the numerous fields I have visited, but knowing the strong prejudice existing against the idea that any knowledge can be obtained beyond the point of the pick and drill, I shall await the result of my first communication in order to know if your Commission is disposed to make use of these discoveries to assist in preventing the present waste of time, labor and treasure, under the present eyesore, or rather want of system in mining.

At the present time mining companies, as a rule, are legalized lotteries, where the manipulators take the prizes and the general public the blanks; the wealth of the West being absorbed into the overflowing coffers of the few.

For various reasons, I attribute mineral deposits to the magnetic currents which, I have previously stated, I find to exist. 1st, I find metals that are the least sensitive to magnetic influence are found in paying quantities only in the line of the older formations. 2d, I find examples of ore from the second formation showing native gold, native silver, black sulphurets of silver, silver glance, zinc-blende, and iron and copper pyrites all separate and detached, each from the other in the same sample. If the deposit was formed by heat in a melted condition or by infiltration, the deposit would have been found in the form of an alloy. The iron and copper ranges of Lake Superior region are but a few miles apart. If the deposits were formed by any of the means now advocated by scientists, some of the Portage lake copper would have found its way into the iron range of Marquette, from the latter point to L'Anse bay. Again, here I find the fifth formation producing iron only, and the sixth copper; these veins thoroughly impregnated with the metals belonging to them, in close proximity to older veins carrying the "noble" metals.

The Jordan and Old Telegraph mines of Utah (the sixth formation) have yielded and yield immense masses of lead ore, but contain only from 11 to 25 ounces silver and a trace of gold per ton, except at points of contact with older formations, where hunches of ore assaying up into the hundreds of ounces are obtained. Again, in the old workings of the Winnemuck (also of Bingham canyon) a vein of the fourth formation yielded average assays of 60% lead and 60 ounces silver per ton. At the crossing of two older formations, masses of ore were encountered assaying 500 ounces per ton. A slip of 80 feet occurs in the lower workings, causing a displacement of the vein. I could cite other instances to prove the correctness of my theory.

From my own observations I should judge that fissures start from a great depth, probably many miles (perhaps thousands) from the point of outcrop, breaking through the earth's crust at points of least resistance, where fractures

have been caused by earlier upheavals, forming vast mineral belts, consisting of groups of ledges, each group possessing different combinations or variety of metals. As this starting point of each group (as they all have different dips) may be many miles away from other groups, each group cutting different metallic deposits, the electric currents impregnate the fissures with the variety or varieties of metals encountered along their course.

I am now in the employ of the Isabelle Gold and Silver mining company (limited), of London, Lonis Chalmers, Esq., Manager. This company is engaged in running a long tunnel to strike a group of ledges at a great depth. Several months ago I made a survey of the various formations and stratifications they would encounter, giving their cleavage and fractures. They are now in something over 1,000 feet, and the workings thus far demonstrate the correctness of my survey. I would state, there is nothing in the appearance of the formation at the surface where exposed to indicate the various changes they have already and will in future encounter. Yours respectfully,

Geo. W. Jones.

The Como Mining District, Nevada.

EDITORS PRESS:—If Virginia City can boast of its Mount Davidson, and of that wonderful ore channel, the Comstock lode, trending down beneath its giant shadows, so we are able to boast at Como of our Mount Lincoln, which is 540 feet higher than Mount Davidson, and our Como lode. We have here with a reasonable degree, the certainty of the permanency and reliability of metal-bearing lodes, the topographical, geological and lithological structure of the country in this vicinity being the same as on the Comstock lode. In a country like Nevada, where the surface is everywhere distorted and corrugated by tremendous eruptive forces, vast sums of money might be saved, and innumerable disastrous failures might be avoided by simply noting the trend and position of the volcanic dykes and of the eruptive ridges, which were unquestionably the direct cause of the faultings, defections and other perplexing disturbances so frequently encountered in the quartz veins of the great basins of this State. If a mining engineer can ascertain with reasonable certainty the source of a local disturbance or fault in the quartz vein, he may frequently succeed in regaining an apparently lost lode, and save from abandonment an extremely valuable property. The Como lode, which was in the market from 1860 to 1863, has been abandoned since 1863, until last summer people started sinking shafts, which have achieved brilliant results.

The Eureka shaft at a depth of 75 feet has ores which on an average assay \$52. The Chieftain shaft at a depth of 200 feet has ores assaying \$62. The West-Rapidan shaft at a depth of 175 feet has ores assaying \$336. The Yellow Jacket, Mayday, Sierra Nevada, Buckeye, Ohio, Sunrise, Como, Consolidated Como, Star of the West and the Ceresus mines are of equal richness.

The Como lode rests upon an elevated plateau 800 feet higher than Virginia City, at a point about 20 miles southeast from Virginia City. The road is a good one, having from Dayton an easy regular grade, all the way to the summit; but the dismal black walls of basalt, and the fantastic pyramids of scoria and other volcanic vestiges which flank the way on either side, are neither picturesque nor encouraging. Upon emerging from this plutonic chasm, into the bright sunlight and pure air of the elevated mesa, the scene is one of enchanting grandeur. Away to the northwest Mt. Davidson lifts its isolated crest, Virginia City, Gold Hill, Silver City, Dayton and Sutroville are a splendid panorama, seen from our place, while circling far away to the south and west the white domes of the Sierra Nevada glitter in the sunlight with indescribable grandeur. The eastern horizon is scarred and marred by the black trachytic cops of the Diamond range. There is a marked and encouraging change in the lithological conditions of our immediate surroundings, instead of the weird, unsightly, volcanic masses of the deep canyons, the entire bed of the broad plateau is composed of porphyry, diorite and other rocks identical with those of the Comstock. The surface lands of the district are by no means level, on the contrary the entire mesa is corrugated by elevated ridges, and by deep depressions and canyons. The outcrop of the Como lode indicates a strong and permanent ledge, and although the work which has been accomplished in the way of its developments is extremely superficial and imperfect, yet sufficient has been done to prove that the ledge in its immediate vicinity is surprisingly rich in gold and silver. We have here 12 houses, two boarding-houses and one saloon. Inside of 30 days we will enjoy the rattling sound of our new 10-stamp mill; a 5-stamp mill has also been contracted for. The townsite, located on 26th of July, has been surveyed by the County Surveyor to apply for a patent, to prevent the great troubles mining towns generally have to go through by jumpers. Business and mining men will do well to investigate this district. There is a great field for an energetic man to make money. Wood costs \$6, instead of \$14 as on the Comstock, and there is free water for household and milling purposes. Parties inquiring of the undersigned will receive cheerful answers.

WM. ROSE.

Sun Dance Among the Sioux.

In our last issue we published a few remarks about Indian peculiarities, particularly with reference to dancing. In the same connection, the following graphic description of this annual "sun dance" of the Sioux nation, which took place near the Poplar river, in Montana Territory, about three weeks ago, will prove interesting. The account is taken from a letter received at the Interior Department, from Dr. T. Woodbridge, agency physician for the Fort Peck agency. The Doctor says:

I have just witnessed the great Indian festival of the "sun dance," or worship of the sun. Great preparations had been made for it, and everything was on the grandest scale. The city of lodges was moved, and the Indians encamped on a beautiful plain inclosing a hollow square large enough for the movements of thousands of horsemen. In the center the great pavilion or medicine lodge was erected, 150 feet in diameter, the outside formed of small posts of green poplar and willow, thickly interwoven with green branches. Resting on this and on a rude framework within, all around for about 20 feet the space was covered with buffalo skins, forming the "dress circle," with places assigned to the musicians and actors or dancers. In the center was the great medicine pole, 50 feet high. The diameter of the central space, about 100 feet, was open to the broad sunlight.

Only the men occupied the deep circle, where they were feasted during the performance of 28 continuous hours, during which time about 40 dogs were immolated and eaten, besides large quantities of buffalo meat, wild-turkey heads, and hot caldrons of other eatables that are nameless. The audience was composed of about 5,000 Indians, but as only the men occupied the circle within, the common people, women and boys, had to be satisfied by viewing the performance through the wide entrance or through the enterstices in the leafy barriers. All had on their holiday attire. The dresses of some of the chiefs, and those acting as directors or priests, were gorgeous.

When all was prepared, amid the waving of banners, music, and the loud shouting of the assembled throng, over 50 braves entered—each an Apollo—painted and naked to the waist, except a profusion of ornaments, with headdresses of beautiful feathers, their black, glossy hair reaching down to their lower garments, which were most beautifully and artistically arranged. Each carried in his hand an ornamented whistle, made from the bone of an eagle's wing, which was blown shrilly during the dancing. Each also carried a bouquet, composed mostly of the wild sage. Their appearance and reception were grand and imposing.

The first afternoon's performance would have been called wonderful for display of heroism and power to endure and suffer. Many had from 50 to 200 pieces cut out of the living flesh from their arms and back. The dance was kept up all night with unabated fervor, every performance having something new and startling. But in the morning torture reigned supreme, men dancing with two, three and four buffalo heads suspended from holes cut in their flesh. One Indian dragged on the ground eight buffalo heads fastened to the flesh of his back, and in the stooping posture he was forced to assume they had lacerated or torn the cuts in his back to the extent of three inches. Others were held by four different cords, two in the breast and two in the back, fastened to four stakes; and still others were fastened to the center pole with ropes, which were fastened to the breast and back. Some, in addition to being fastened by the flesh of their breasts, had buffalo heads suspended from the back, and they would be seized by the hanging heads and jerked until one would think their life would be forfeited; others made frantic efforts to break loose, and I often noticed the integument to be stretched three or four inches from the body. Some fell faint and exhausted, and with wild shouts, the din of music and weird songs, made of it a perfect pandemonium.

The dancers neither took food, sleep nor water during the festival. Their dancing, their invocations and their prayers were fervent. They laid their faces on the buffalo heads while praying for success in hunting, and the priest wept and asked the Great Spirit to give them success in the chase and let them have food for their wives and children; also, to give them plenty of horses, to prosper them and help them to subdue their enemies. The sod was carefully removed in a spot four feet square, and within a white cross was made. Their liberality was unbounded. Over 200 horses were given away, besides great quantities of other articles.

ANCIENT TIMBER.—The oldest timber in the world which has been used by man, is supposed to be that found in the ancient temples of Egypt. It is found as dovetails in connection with stonework which is known to be at least 4,000 years old. These dovetails appear to be of tamarisk or shittim-wood, of which the ark is said to have been constructed, a sacred tree in ancient Egypt, and now rarely found in the valley of the Nile.

WHERE TO FIND PLATINUM.—Mr. Edison has received over 3,000 replies to his inquiries for platinum. It can be had from California, North Carolina, Idaho, Dakota, Washington Territory, Oregon, Colorado, Arizona, New Mexico and British Columbia. Many samples of other valuable metals are daily received by him.

MECHANICAL

PROGRESS.

Removing Boiler Incrustations.

In order to remove incrustations from the tubes of locomotives, marine and other steam generators, Hermann Esser, of Karlsruhe, says the London Mining Journal, proposes to cause the tubes to revolve in contact with a number of comparatively small hard bodies. For the purposes of the invention pebbles are suitable. To effect the removal expeditiously the tube is caused to revolve rapidly, and a receptacle containing the pebbles is traversed to and fro along the tube, the pebbles being pressed into contact with the tube, and being kept wet by means of a stream of water. In an apparatus designed for the purpose a bed similar in form to a lathe bed is provided with fast and following headstocks. The spindle is provided with a scroll-ebuck or a suitable chuck for gripping the tube. For convenience the spindle is held by means of a detent and wheel at the time when the tube has to be inserted or removed. The following headstock is fitted with a spindle which is free to revolve in bearings, and is provided with a conical end to enter the tube, and with a tail-pin which takes the thrust. A sliding carriage carries a perforated cradle which holds the pebbles. The cradle is provided with a hinged or removable cover, which, when in position, is pressed towards the tube by means of a spring or weight. The parts are so formed and arranged that the tube is entirely surrounded by pebbles, which are pressed against the tube. A water-pipe or cock is connected by means of an india-rubber tube with a water supply pipe, or is otherwise so connected that the movement of the carriage will not interrupt the water supply. The carriage is traversed to and fro during the rotation of the tube, and the abrading action of the pebbles removes the incrustation, and the particles removed are washed away by the stream of water. A receptacle to receive the water and mud is formed below the cradle, and the receptacle communicates by means of a pipe or spout with a gutter, which runs along the bank of the bed convey away the water and matters removed from the tube.

IMPROVEMENTS IN COLLIERY WINDING GEAR. A new system of winding gear, known as Koepe's patent, which has already been adopted at many of the collieries in Germany and France, is being introduced at some of the collieries in this country, and Messrs. Nasmyth, Wilson & Co., of the Bridgewater foundry, Patricroft, near Manchester, are at present constructing engines and winding apparatus on this principle for the Bestwood Coal Company, Nottingham. The principal feature in the new system consists in doing away with the ordinary draw and the great weight of rope, which, in deep mines, is a very great strain upon the engine. In this system the cages are attached one to each end of the winding rope which passes over the head gear pulleys and over a winding pulley, which takes the place of the draw, and a balance rope of the same weight as the winding rope is fixed to the bottom of each of the cages, the balance rope hanging freely in the shaft and the lower end being allowed to dip into the sump at the bottom. By this method, however deep the shaft, the ropes and cages are always balanced, and the engine in winding up has only to overcome the weight of the coal in the tubs and the friction of the working parts; a steady engine speed is secured, whilst considerably less engine power is required and the risk of overwinding is very much reduced. The system has, we are informed, answered satisfactorily where it has been tried, and is spoken highly of by some mining engineers.—*Colliery Guardian*.

THE ORIGIN OF MACHINE-MADE PENS.—Joseph Gillott, the first to employ machinery in the manufacture of steel pens, was originally a maker of huckles and other "steel toys," working alone in a garret in a Birmingham "slum." At this time he was engaged to a young woman in his own rank in life, whose two brothers were working, in about the same style as himself, on hand-made pens. Gillott thought he could better the processes employed, and worked secretly in his garret until he had made a press and other appliances, by which he could make 20 times as many pens in a day, and better pens, than was possible under the old methods. He found ready sale for them, and soon the demand outgrew his power of production. At this juncture his sweetheart agreed to his proposal that they should marry and work together, little dreaming of the ultimate issue of their enterprise. In after years Mr. Gillott used to tell how, on the very morning of his marriage, he began and finished a gross of pens, and sold them for £7 4s, before going to church.—*Scientific American*.

INSTRUMENT TO DETECT COLOR BLINDNESS.—Herr Hirschberg has devised an improved instrument for detecting color blindness, which may be of interest, as the incapacity of many employees of railroads, steamboats, etc., to distinguish colors is attracting much attention in this country. His apparatus is an adaptation of the spectroscope to the requirements of the special case. The spectroscope contains a fixed and a movable collimator tube, so that one spectrum can be moved above the other. By means of a slide in the eye-piece any portion of the double spectrum may be presented to the eye alone, and will then constitute a good object for comparison.

An Induction Balance.

Prof. J. E. Hughes has lately devised an instrument which promises to be of great use in determining the amount of the constituents of alloys. It is based upon the principle that the induced current in a secondary coil depends upon the character and amount of metal which forms the core of this primary. A portion of the apparatus Prof. Hughes calls a sonometer; this consists merely of two primary coils which are placed with opposing poles about a meter apart on a divided scale. Between them slips a secondary coil which is connected with a telephone. If the primary coils are exactly equal, and are traversed by the same electric current, one will bear no sound when the secondary coil is exactly between the primary coils. This point of balance is called the zero of the sonometer. The circuit running through the primary coils is provided with a microphone, and a clock ticking upon the support of the microphone supplies the necessary change of resistance in the electric circuit. If the equality of the sides of the sonometer is disturbed by the introduction of metals on one side or the other, the telephone announces the inequality and the secondary coil has to be moved near one primary coil than another. The number of degrees moved is a relative measure of the difference of the metals. The extreme sensitiveness of this balance is shown by numerous experiments. It is also of use as a coin detector—any difference in the quantity or quality of the metal being instantly shown. W. Chandler Roberts, chemist of the mint, has tested Prof. Hughes' balance, and gives a number of curves produced by different alloys, and shows that the balance can detect smaller quantities of metals in the composition of alloys than the methods hitherto used. He suggests also "that the balance may afford a simple means of detecting variations in the molecular structure of alloys and for detecting allotropy in metals with greater accuracy than has hitherto been possible."—*Phil. Mag.*

ELECTRIC JEWELRY.—A curious application of electricity appears in some specimens of electric jewelry recently described in *La Nature*. Among the specimens are a scarf pin consisting of a small golden rabbit holding a liliputian mallet in each paw, with which it beats a roll on a small golden gong; a golden skull with movable diamond eyes and an articulated jaw. This is also a scarf pin, and its eyes and jaw are made to move in a singular manner. A bird is also shown which is an ornament for the head dress. It is of gold, thickly studded with diamonds. These pieces are connected by a fine concealed wire with a small battery carried in the vest pocket. When the battery is made to operate, the rabbit will strike the gong, the bird will move its wings, and the skull will roll its eyes and gnash its teeth. The battery consists of a zinc and carbon couple contained in a hermetically closed vulcanite case, the zinc and carbon occupying the upper half of the case and the exciting fluid the lower half of the case. When the case is in a vertical position the exciting fluid does not touch the zinc or carbon, but when it is inverted or placed horizontally, the fluid comes into contact with the zinc and carbon, and the current traverses the coils of the diminutive magnets, which operate the mechanism of the pieces. The mechanism is much like that of an ordinary vibrating electric bell.

MANIPULATION OF STEEL.—At the recent meeting of the Iron and Steel Institute at Liverpool, considerable discussion followed the reading, by Mr. Ratcliffe, upon the welding of steel. Mr. Ratcliffe maintained that it was not healthy for the steel to be crystalline. No matter how they worked a piece of iron or steel under the hammer, they got comparatively very little fiber produced in it—in fact, they might make a fibrous iron into a crystalline iron with very simple hammering. He knew of no other process by which they could produce as good a fiber as by rolling. All steel to start with was crystalline. Next to rolling the best way to get fiber in iron and steel was by means of hydraulic pressure, the effect of which was to squeeze and gradually draw the crystals out, whereas, with hammering, it simply knocked them together, and they had hardly time to think where they should stretch.

CACTUS MATTRESSES.—Some ancient Comstockers think they have a fortune in Lower California. There is a plant growing there profusely and promiscuously, a species of dwarf cactuses, which, when properly reduced, makes the best kind of material for mattresses. A hundred thousand dollars have been spent in trying to produce a machine to do this work, but nothing succeeded until a company, a part of whom are Comstockers, fell upon a genius who for \$400 completed an experimental machine, which in the most rapid manner produces a mass of white, elastic fiber. These gentlemen assert that they can reduce the cost of mattresses 40% and then make profit, which will cause every man in the company to feel like a thief.—*Arizona Sentinel*.

A CHANCE FOR INVENTORS.—A Buffalo (N. Y.) grape sugar company offers \$10,000 "for any appliance to our boilers that will consume smoke and not diminish the quantity of steam now obtained." Perhaps some device could be applied at our Mint to consume the acid fumes belched from the chimney.

SCIENTIFIC

PROGRESS.

Forests and Meteorology.

An important paper in *Polybiblion* on this subject gives the results of observations made during the last six years under trees and not far from the edge of a forest, and also in the plain and far from all trees. 1. Forests increase the quantity of meteoric waters which fall on the ground, and thus favor the growth of springs and of underground waters. 2. In a forest region the ground receives as much and more water under cover of the trees than the uncovered ground of regions with little or no wood. 3. The cover of the trees of a forest diminishes to a large degree the evaporation of the water received by the ground, and thus contributes to the maintenance of the moisture of the latter and to the regularity of the flow of water sources. 4. The temperature in a forest is much less unequal than in the open, although, on the whole, it may be little lower; but the minima there are constantly higher, and the maxima lower than in regions not covered with wood.

These observations have been made in the neighborhood of Nancy, and by the pupils of the School of Forestry of that city, under the direction of M. Mathieu, sub-director of the school. On the other hand, M. Fautrat, when sub-inspector of forests at Senlis, made during four years, but on a different method, observations on forestal meteorology which fully and completely corroborate, in certain respects, those of M. Mathieu. The laws which seem to follow from the figures given by M. Fautrat, as well as an inspection of the curves which graphically represent them, are as follows:

1. It rains more abundantly, under identical circumstances, over forests than over non-wooded ground, and most abundantly over forests with trees in a green condition. 2. The degree of saturation of the air by moisture is greater above forests than over non-wooded ground, and much greater over masses of *Pinus sylvestris* than over masses of leaved species. 3. The leafage and branches of leaved trees intercept one-third, and those of resinous trees the half of the rain water, which afterward returns to the atmosphere by evaporation. On the other hand, these same leaves and branches restrain the evaporation of the water which reaches the ground, and that evaporation is nearly four times less under a mass of leaved forest than in the open, and two and one-third times only under a mass of pines. 4. The laws of the change of temperature out of and under wood are similar to those which result from the observations of M. Mathieu. The general conclusions seem to be that forests regulate the function of water, and exercise on the temperature, as on the atmosphere, an effect of "ponderation" and equilibrium.

ELECTRICITY IN FLOWERS.—Last evening a gentleman of this city accidentally made a most singular discovery respecting the electrical influence of the ordinary morning glory vines. Seated near the lattice work, over which the vine was trained, his attention was attracted to a single little branch tipped with a growing line extending straight out from the rest, and speculated within himself whether the tiny hairs with which the stem was clothed were not placed there for the purpose of conducting the electric fluid of the atmosphere to the plant. In order to continue this investigation he approached his finger within a half inch of it, and was amazed to observe a slight—almost imperceptible—yet unmistakable motion of the stem. As he pushed his finger a little nearer the stem trembled very visibly and was seemingly attracted and repelled from him. The hairs which he noticed before did not move, but remained erect. There was no wind at the time and the motion was purely an induced one. After this interesting experiment he placed the end of his finger within a short distance of the growing bud and slowly moved in a circular direction. The stem followed the motion until it was bent in the shape of a letter C, and when the finger was withdrawn instantly regained its former straight position. This last experiment was witnessed by several persons, all of whom tried it with varying success.—*Lafayette (Ind.) Courier*.

BLOOD OF THE LOBSTER.—Harless found copper in the blood of crustaceans, cephalopods and gastropods. It has long been known that the blood of these three groups of invertebrates changes its color when it is exposed to the air. Jolyet and Regnard concluded that the blood of the crab contains two coloring substances, one blue and the other red. The first is united with the albumen, which, when coagulated by alcohol, has a clear blue tint; the red dye remains in solution in the alcoholic filtrate. Leon Fredericq finds the same principles in the blood of the lobster, but the red contains no metal; it does not change color in oxygen or in a vacuum; it is not always present. The blue seems to be identical with hemocyanine and contains copper. The saline portion of the blood has a composition almost identical with that of the water in which the lobster lives. The hemocyanine easily unites and parts with oxygen and thus acts as a stimulant to respiration, the nutritive function of the blood being confined to the plasma.—*Bull. de l'Acad. Roy. de Belgique*.

THE COLORING OF AUTUMN LEAVES.—The green coloring matter of leaves has been recently reinvestigated by M. Fremy, and his results shed some light on the cause of the coloration of autumn leaves, although further study is still necessary to account for the manifold brilliant tints to be found in American autumn foliage. M. Fremy's previous studies on chlorophyll tended to prove that it was not a simple coloring matter, but composed of two different substances—a yellow which he named Phylloxanthin and a bluish green named Phyllocyanin acid. His more recent investigations have had for their object to ascertain in what conditions these constituents of chlorophyll exist in the organic tissue, whether mixed or combined, suspended in the liquid or united with the cellular tissue. By means of experiments, he finds that they exist in the leaves as a mere mixture. It yet remains to ascertain whether the phyllocyanin acid existed in a free state, or combined with a base, or united with the cellular tissue by a sort of capillary affinity. Analysis showed the presence of a notable quantity of potassa. The green matter of leaves, then, can be considered as a phyllocyanate of potassa mixed with phylloxanthin. "It has long been known," says M. Fremy, "that leaves in autumn lose their green appearance, changing to yellow, and also give off a large portion of their alkali. Now we know that this process depends upon the decomposition of the phyllocyanate of potassa."—*Ex.*

THE CAMPHOR EDDIES.—If a small bit of camphor is laid upon water it begins turning and moving about with great rapidity. If a few grains of locopodium or other light powder have been previously scattered on the water they are drawn towards the camphor by eddies in an inverse direction. These phenomena were first observed in 1748 by Romien, who attributed them to the difference of electricity between the water and the camphor. Subsequent investigators thought they might be due to the camphor vapor striking the water and producing a recoil. M. Cassamajor has resumed the study of the question and adopted the view of Romien. He instances the following crucial experiment. At the same time that the bits of camphor are thrown upon the water insert a glass rod which has been rubbed with flannel; the motion immediately stops. If the electricity is removed from the rod by rubbing it with tin foil, it loses its power of checking the eddies.—*Les Mondes*.

INCOMBUSTIBLE AND IMPERMEABLE WOOD.—M. Folbacci uses the following preparation: Sulphate of zinc 55 lbs, potash 22 lbs, alum 44 lbs, oxide of manganese 22 lbs, sulphuric acid of 60°, 22 lbs, water 55 lbs. All the solid ingredients are put into a boiler containing the water at 45° C. (113° F.), and as soon as they are dissolved the sulphuric acid is poured in gradually until the mass is completely saturated. The pieces of wood are kept about five centimeters (1.97 in.) apart, and after three hours' boiling they are dried in the open air. The natural appearance of the wood is not changed; to whatever heat it is subjected, it resists combustion, the surface being simply covered with a thin charred coating which is easily rubbed off.—*Ann. du Genie Civil*.

ANIMAL ELECTRICITY.—An important paper on the results of recent researches in animal electricity is published in the *Nature*. The author, Dr. L. Herman, states that the whole of the electrical phenomena of muscle and nerve may be readily deduced from a few very simple propositions. Irritable protoplasm responds both to destructive and to exciting influences by an electromotive sign. The altered substance takes on a negative potential with respect to the unaltered. This, together with the doctrines of internal transverse polarization and of the polarizational increment of excitation, appears fully competent to explain all the facts hitherto observed.

AMERICAN SCIENTIFIC ASSOCIATION.—Next year the American Association for the Advancement of Science will hold its meetings in Boston, commencing on the last Wednesday of August. The officers are: President—L. H. Morgan, of Rochester; Vice-President, Section A—Asaph Hall, of Washington; Vice-President, Section B—Alexander Agassiz, of Cambridge, Mass.; Permanent Secretary—F. W. Putnam, of Cambridge, Mass.; General Secretary—John K. Rees, of St. Louis; Secretary of Section A—Henry B. Nason, of Troy, New York; Secretary of Section B—C. V. Riley, of St. Louis; Treasurer—William S. Vaux, of Philadelphia.

FIRE-DAMP IN MINES.—For the purpose of ascertaining the presence of fire-damp in mines, Millard and Le Chatelier use a lit jet of hydrogen, which gives a larger and more distinct blue aureole than the flame of the common safety lamp when the quantity of the dangerous gas is even very small. This expedient has revealed the presence of 0.25% of fire-damp. The flame which is inclosed in a copper tube, is viewed through a lens in the side of the tube.

IGNITING TINDER.—The common experiment of igniting tinder by compression in a glass tube does not always succeed; the tinder may not be ignited, or may not retain its glow after the piston is withdrawn. Tyndall uses sulphide of carbon vapor instead of tinder. Hofmann says hotb may be advantageously replaced with gun cotton.

Mining Share Market.

We know from the daily papers that there is a Stock Exchange in this city, but outside of that means of information the fact would hardly be known to the uninterested public, for the reason that the business that has been done for the past week has been void of excitement. Whatever transactions have occurred have been in the quiet transfer of mining stocks upon their own merits as an investment, and not upon any demand for speculative purposes. The market may be termed sluggish, without a ripple of excitement. The rich developments in the Sierra Nevada have failed to bring about a "boom," which would have occurred in former times to such an extent as to be the ruin of many and the enrichment of a few. Many of the stocks have been up and down, in a small degree affording buyers an opportunity to make their daily stipend of profits, and preventing any great loss if caught on the down grade. Sierra Nevada does not seem to be considered in making calculations, while much is expected of Union Con. The Bodies opened steady, but declined one-half at the end of the week. The fluctuations have been constant, and at the close of our report left the favorite Comstocks on the rise with a feeling of strength. There are no prophets in the market, for the reason that the indications which generally foretell the condition of the business are either absent altogether, or are considered unreliable. We may safely assume, however, that the condition of the mining share market for the past few weeks is an indication of a calmer disposition in those whose occupation leads them stockward, and a desire to confine their attention to quick sales and small profits.

The New Water Pipe.

Mr. John P. Culver, civil and hydraulic engineer of this city, formerly chief engineer of various water works in the East, has for the past twelve years been perfecting a water pipe, based upon thin sheets of iron and asphalt. Notwithstanding repeated and discouraging failures in this country and abroad, the efforts of inventors have never relaxed, and entire success has at last been achieved, continued through a period of fifty years. Several years of trial at the East under pressure of 75 pounds to the square inch fully settles their value. These pipes are composed of alternate layers of thin sheets of wrought iron, coiled in convolute folds, cemented together by interfused asphaltum. They are wonderfully strong, durable and cheap. No coal tar is used in their manufacture. It is confidently predicted that this is the coming water pipe, and is certainly a long-needed improvement. The strength of these tubes is truly a matter of great surprise, in fact, wonderful, which, coupled with so many other advantages, that it seems a great stride in that branch of hydraulic engineering. The object long aimed at has been to preserve the iron from rust, and in this instance it is thoroughly accomplished. No rivets are used in the pipe, the bond of the asphaltum being greater than the tensile strength of the iron, a six-inch pipe made of two thicknesses of No. 28 iron withstanding this great internal strain of over 300 pounds to the square inch, without rupture. Mr. Culver has taken out many patents to cover this invention, and there is no doubt but what he has accomplished a result creditable to himself, and meeting a need that cannot but make a great local, legitimate and beneficial enterprise. The pipes are soon to be manufactured here, and we shall treat at greater length on the subject hereafter.

It is now stated that Sitting Bull and his entire following, numbering 6,000 persons, are waiting for the Missouri to freeze over, in order to return to the American side of the border.

The body found lately on the shore of Lake Michigan has been identified as that of Burr, who accompanied Prof. Wise in the balloon Pathfinder.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

AMADOR CON.—Ledger, Oct. 25: Everything is moving along prosperously with this old mine of Sutter Creek. The old building upon the new shaft is having the finishing touches put on it. It is built in a substantial manner. A car track is also being laid from the new rock dump to the mill. It is expected to have everything in shape for taking out rock early next spring.

TIBBETTS CLAIM.—Allen Tibbetts, who owns this claim, which is located above the famous Mahoney, of Sutter Creek, has purchased a five-stamp mill, which he intends erecting on the claim. The mill was purchased in Volcano district. Tibbetts is present engaged in tearing it down, and shipping it to Sutter Creek. Two men are also at work grading a site for the reception of the mill.

MINE SOLD.—Dispatch, Oct. 25: The old Sorocco quartz mine, situated on Elise creek, near Volcano was sold a few days ago, by G. W. Porter, to Cummings & Co., of San Francisco, for the sum of \$10,000. We understand that the new owners intend to commence work immediately and thoroughly prospect the mine.

ITEMS.—Sentinel, Oct. 29: The Downs mine, at Volcano, is still progressing finely. At a depth of 310 ft., 20 ft. each way from the shaft, the ledge shows a width of four to five ft. Fine gouge is found on the footwall, making it easy and cheap to sink and to take out ore. A rich body of ore has been struck in the Maryland, near Drytown.

CALAVERAS.

SAN PEDRO.—Calaveras Chronicle, Oct. 25: Work on the San Pedro, at Mosquito, is progressing steadily. The new shaft has been sunk to a depth of about 250 ft., and drifts are now being run to strike the pay chimney.

THE DUREYA HYDRAULIC.—Piping is to be commenced in the Dureya hydraulic, Chills gulch, next Monday.

BIG BLAST IN THE BONANZA.—A blast of 650 pounds of powder was exploded in the Bonanza hydraulic, Moser & Co. owners, Monday afternoon last. A tunnel was run into the face of the bank a distance of 30 ft. From the inner end of the tunnel a lateral drift was run 20 ft., and then turning at right angles was run still further into the hill. The tunnel and drift were then thoroughly and securely tamped and the powder exploded. We learn that the blast did excellent work, shattering and pulverizing the gravel bank so that it can be readily pipped. Everything is in readiness now at the Bonanza for turning on the water, and as soon as that important adjunct to mining can be obtained, operations will be inaugurated.

EXTRA.—Angelo Echo, Bennett & Co. are now engaged in sinking a shaft on the Raspberry mine, with brilliant prospects ahead. They have sunk their shaft to a depth of 24 ft. The Raspberry claim is one of the best in this vicinity. The Fair Play mine is opened by two tunnels, the upper one nearly 200 ft. and the lower one now about 300 ft., and both are connected by a winze. The mill in the Raspberry mine is to have 10 stamps, with new and complete amalgamating arrangements, and is situated at the mouth of the lower tunnel.

EL DORADO.—GERMAN MINE.—*Mountain Democrat, Oct. 25:* The German mine, at Mosquito, is progressing steadily. The new shaft has been sunk to a depth of about 250 ft., and drifts are now being run to strike the pay chimney.

LUCKY PROSPECTORS.—Up near the line of the ditch, far up the mountain back of the German mine, Loafers' hollow, two prospectors were last Saturday getting from \$2 to \$3 to the pan from a considerable deposit of ferruginous slate and decomposed quartz they had just opened up. About a mile thence, far up the mountain on the opposite side of the ditch, Messrs. Chas. and others have sunk a shaft 15 or 20 ft. through a similar deposit, from which they have taken as high as \$7 to the pan.

FRESNO. RICH STRIKE.—*The Fresno Republican* says: In sinking the main shaft at the Hanover mine, a few days since, a rich vein of gold-bearing quartz was struck at a depth of 150 ft., 14 inches in thickness. Work has been pushed ahead in following the vein down, the quartz increasing in thickness and growing richer as depth is gained. At the present time they are down 187 ft., and the vein is over two ft. in thickness, and the ore assays over \$100 per ton. Steam hoisting works are to be erected at once. The mine is situated on the north side of the San Joaquin, about 30 miles from Fresno and one mile east of Fine Gold.

QUICKSILVER.—Fresno county, in addition to her valuable gold and silver mines in the Sierras, has a large territory in the Coast range that contains vast deposits of quicksilver ore. The New Idria quicksilver mine is situated in the Coast range, about 10 miles west of Fresno, and is one of the most valuable and productive in the world. Many other valuable quicksilver mines are located in the same vicinity, but they have not been worked to any great extent the past few years, owing to the extreme low price of quicksilver. Now, however, they will undoubtedly be started up again, as the present price will pay a handsome profit above the cost of production.

INYO. BISHOP CREEK DISTRICT.—*Independent, Oct. 25:* This district was recently formed from the Antelope. The western boundary was extended from a point on Owens river along the north line of the county in a westerly course to a point where the line intersects the line of the Sierra Nevada district, thence southerly along the line of said district to the line of Cummings district; thence along the line of Cummings district in a southerly course to a point on Big Pine creek; to the southeast corner of Cummings district, thence along Big Pine creek in an easterly course to a point on Owens river opposite the mouth of Big Pine creek.

PANAMINT.—The Stedfeldt furnace will not be put to use yet awhile, the mill having plenty of free milling ore on hand to keep it busy for some time to come. Panamint now has a well-stocked store where all ordinary supplies can be obtained at reasonable rates.

NEW MINES.—The Indiana mine, owned by Messrs. Boley & Tuttle, near Swansea, is turning out some of the richest silver ore ever seen in California. Several assays made by Mr. Woodhull of the last ore taken out averages 323.72 ounces per ton. Work is being prosecuted in following the vein in the tunnel, from which the ore is taken. The vein is perfect and continuous and is gradually widening. The tunnel is in nearly 200 ft. Messrs. Boley & Tuttle are also opening a new mine near the Indiana. They have a two-foot vein, the croppings of which assay 127 ounces in silver. On the same hill, in a direct line with the Indiana north one and a half miles is the Flagstaff mine having ore which assays 400 ounces in silver per ton.

MONO. MARYLAND CON.—*News, Oct. 26:* The work of sinking the main shaft is progressing rapidly, and every effort is being put forth to attain depth. When the 250 level in the main shaft is reached, where a crosscut at the foot of the old incline has already been run, the company will resume the extraction of ore from the main ledge in the north and south drifts; at the same time sinking in the main shaft will be continued indefinitely.

NOONDAY.—The joint shaft is down 450 ft. Crosscut east from the 300 level in 148 ft. crosscut from same level west, in 115 ft. From the 300 station have drifted

on vein No. 1, south, 50 ft.; on the same vein north, 93 ft. Have drilled on vein No. 2, from 300 level, south, 36 ft.; north on same vein and station, 23 ft. Vein No. 1 is about two ft. in width, strong and well defined, and carries good milling ore. Vein No. 2 is about five ft. wide, strong and regular. Quartz unmineralized with porphyry and giving high assays. The vein cut from the 212 level is very large and strong, all ore assays from which average \$30 per ton. This vein is from 5 to 10 ft. wide. A drift has been run south on this vein from point of intersection 50 ft. Connection has been made from west crosscut on the 212 level with the Noonday drift from the 200 station. This gives a continuous line of drift on the Noonday ledge of about 800 ft.

TRIOA.—Main shaft now down a depth of 445 ft. The Syndicate drift has been advanced to a length of 507 ft. in most favorable ground. Halls commenced a drift from the bottom of the Ralston winze, on the 020 level, and a west crosscut from same level has been advanced 18 ft. toward No. 3 drift. East crosscut, same level, is now in 23 ft., and the ground looks decidedly favorable. Have completed winze from the 320 to the 620 level; the connection thereby made offering sufficient air to dispense plenty through the winze.

BOULE TUNNEL.—Now in 1260 ft., the character of the ground being very favorable, with much iron-stained porphyry in the face. Are making from two and one-half to three ft. per day. An everything looks remarkably well for the future of this property. Work will be resumed at the 900 station within a few days, when important developments may be looked for. Air in the tunnel continues good, and the men work with comfort in any portion of the property.

UNIVERSITY.—Main shaft down 160 ft.; formation at bottom hard, iron-stained porphyry, carrying clay seams with quartz. Timbering is being done as the shaft is sunk. Machinery and everything above ground is in first-class order and running well. Sinking will be continued without interruption until a sufficient depth has been reached, when crosscutting for the ledge will be begun.

SOUTH NOONDAY.—Shaft now down a depth of 48 ft.; the formation, quartz mixed with clay and porphyry. Timbering in a substantial manner all the way from the surface. Late developments in the Noonday property are all pitching east and toward the South Noonday. A shaft house will be placed over the shaft at an early date.

SOUTH HILL.—Work on the north drift from winze No. 2, 350 level, is being carried along vigorously, and is now in a distance of 85 ft. from the winze, holding its regular and well-defined course the entire distance. In the face of this drift the ledge is 6 ft. wide, of good milling ore. Everything working in first-class shape and condition.

RED CLOUD.—In the south drift, on 250 level, have about four ft. of low-grade ore, which will probably mill about 800 per ton. Are raising a chute from this drift, which is in 30 ft.; have two and a half ft. of ore. Are also making an upraise from the east lateral drift; have raised 20 ft. and have two and a half ft. of ore.

ADRENDA.—Since last report have added 25 ft. to the 300 south drift; total distance in from incline, 145 ft. The west crosscut, at the 200 station, is now in 70 ft., face of crosscut in birdseye porphyry. The 300 drift is still in ledge formation. The mine is looking very well.

MAMMOTH.—Mammoth City Herald: The air compressors and drills are kept steadily at work in the lower and middle tunnels. Rock is being steadily shipped from the mine to the mill, which is kept running night and day.

TRUE BLUE TUNNEL.—Now in about 200 ft. from the face, working altogether in vein matter and showing a near approach to the main ledge. The ground is working well, and the tunnel is being driven with all possible dispatch.

NEVADA.

GREAT REPUBLIC.—Grass Valley Union, Oct. 25: This quartz claim, located in the Ralston, near the Summit is showing good prospects. An incline is down upon the ledge 85 ft., at which point it is tapped by a drain tunnel several hundred ft. in length, which carries off the surface water. A contract has recently been let to sink the incline below the level of the tunnel, and this ledge now shows in the shaft a width of three and a half ft., which prospects finely in free gold. Should the prospects continue as favorable as at present, the mine will be put in regular working shape by the erection of steam hoisting works.

WASHINGTON MINE.—The work on the mine is prosecuted diligently. The new shaft is down 140 ft., and is carrying a ledge of from 12 to 18 inches of fine-looking quartz, containing considerable sulphurets. The ground is firm and the ledge solid. The stockholders of the company are in excellent spirits, and the appearance of the mine, which they regard as giving most excellent promise for the future. The pumping rig on the mine is one of the best in the district, being a large water-wheel with ample power at all seasons of the year, which will furnish all necessary power required in pumping and hoisting.

ROCKY BAR MINE.—The drift in this mine that was being run for a connection between the new shaft and the old Chavanne shaft has been completed. The drift was started from both shafts under the supposition that the ledge in both were the same, but it was demonstrated that they were separate ledges, and when the drifts were extended far enough toward each other a crosscut was run to connect them, and upon its completion it was shown that the two ledges are 60 ft. apart, both being of good size and producing fine pay ore. With this connection made an important change in the working of the mine is contemplated, and instead of two sets of machinery being used to do the hoisting, one will be stopped and all the rock hoisted through the Chavanne. This will prove quite an item of saving in the monthly expenses of the mine. The drain drift from the bottom of the Chavanne shaft through to the New York Hill mine has yet about 80 ft. to run, which will take from three to four weeks, when a perfect drainage will be secured for the mine to its present depth of working. The drifts that are now open give access to a large amount of ore, sufficient for one year's work without deeper sinking, and in the meantime the present drifts will be extended and a large body of undeveloped ground opened. There is but little water to be pumped now, and with the drain drift there will be none at all. There are fifteen and 70 men working above and below ground, and this number will be increased during the winter. The mine presents a good appearance throughout, and promise to be among the leading properties of the district.

EAST ORELAND CLAIM.—The Nevada City Transcript says: The above claim is situated on the Live Yankee ledge, adjoining the old Odeum mine on the east. Messrs. Russell & Jamieson are the owners. They have run a tunnel into the sidehill a distance of 700 ft. The first chute was struck 300 ft. from the mouth of the tunnel, but they pushed by it without taking out any of the ore, and after going 400 ft. more struck the chute they had started with the 30 ft. incline in thickness, showing about 30 ft. of ore, which will take from three to four weeks, when a perfect drainage will be secured for the mine to its present depth of working. The drifts that are now open give access to a large amount of ore, sufficient for one year's work without deeper sinking, and in the meantime the present drifts will be extended and a large body of undeveloped ground opened. There is but little water to be pumped now, and with the drain drift there will be none at all. There are fifteen and 70 men working above and below ground, and this number will be increased during the winter. The mine presents a good appearance throughout, and promise to be among the leading properties of the district.

PLACER. DITCH FLAT.—*Forum, Oct. 23:* The miners in this vicinity are busily engaged in preparing for the coming season, working the various gravel and other claims the coming season. Probably no better prospects for a favorable season have existed for several years, and it is confidently believed that the coming season's work will mark an epoch in the history of our mines that will result in a large amount of treasure for the owners and an increased prosperity to all kinds of business.

SIERRA. AIR SHAFT.—*Downville Messenger, Oct. 26:* The parties who have the contract for raising the air shaft in the Highland Mary mine, at Wahoo, are pushing their work along rapidly, and expect to get through in a few weeks. They are up 150 ft. now, with about as much more to raise.

MONSTER NEGOT.—Nevada City Transcript, Oct. 29: Dr. Holdsworth, the veteran prospector of the mountains, was in town yesterday. He says that about two weeks ago, while working in his blue lead claim at Milton, Sierra county, he took out a nugget that tipped the scales of a Sierra City banker at over a pound and a quarter. There is not a bit of quartz in the mass, and he is going to keep it as a memento. It is the largest piece of gold he ever found in all his experience as a miner. It is worth \$19.50 per ounce.

TRINITY. HOSTETTER GULCH.—The Trinity Journal has information that rich prospects have been obtained from a recently discovered quartz lode on Hostetter gulch.

TUOLUMNE. PIETY HILL.—*Sonora Union Democrat:* Monday morning ground was broken again on Piety hill, in front of E. A. Rodgers' residence, preparatory to going for the vein of quartz that is known to run from the Divoll, Clark and Bray bonanza in front of Rodgers' and back of Cady's house. We learn that parties back of Cady's house have dug and found the vein, other parties are at work below, near the Jewish cemetery, sinking for the vein. The Ferguson and Smith claim near the Divoll & Co., is a different vein overlying the Divoll about 25 ft. Works kept up on it and some rich ore is obtained.

GROVELAND.—Independent, Oct. 25: A correspondent says: Our mining prospects seem to be brightening up wonderfully. The Mt. Jefferson company are still thimdering away with their mill and have quartz enough in eight to last for many months. The Italian company, on Deer flat, will start their mill within two weeks, or as soon as the concentrator, now in process of erection, can be completed. They have several hundred tons of good paying ore on the dump, and plenty more in sight, handy to be got, and wood enough on hand to last six or nine months. The Spring mining company have out about 40 tons of ore, which they are hauling to Big Creek mill, and will commence crushing again this week if the water holds out. Dr. Austin has sold a mine, near Bower Cave, to a New York capitalist for \$3,000, and the new owner is already at work upon it. Work is also being pushed ahead upon the Banderita by its new owners, who recently purchased it for \$50,000. The company that recently purchased the Captain Arkin mine at Coulterville, have now purchased a large mill in Hunter's valley, which they are moving over to their mine, and under the supervision of Mr. Piper, will soon have it in running order.

NEVADA. WASHOE DISTRICT. OPHIR.—Our latest reports are as follows: Main incline has been sunk and timbered to a depth of 92 ft. below the 2400 station, and continued in a favorable-looking vein material, showing streaks of clay and hard ground. On the 2400 level this west crosscut has been advanced 20 ft., through a vein formation corresponding to that exposed in the main incline at that point, and is now in 78 ft. from the east side of the incline.

CON. VIRGINIA.—Ore to the amount of 1,134 tons has been extracted during the past week. Winze on 1500 level is down 45 ft. passing through low-grade ore. CALIFORNIA.—On the 550 level the north drift has been advanced 20 ft., and is now in 100 ft., passing through a vein formation. At the 2250 level in this C and C shaft they are cutting out a station, from which a north drift will be run to intersect the ore vein found on the 2150 level. The pumps continue to work well and handle the water with ease.

SIERRA NEVADA.—The shaft has now reached a point three ft. below the Sierra Nevada 2300 level, and the station set is in place. The bottom still shows streaks of good ore. They have started a drift from this station to connect with the drift being run from the Sierra Nevada incline on their 2300 level.

BULLION.—The main incline has been sunk and timbered a distance of 13 ft., making its total depth 137 ft. below the 2500 level. The bottom is still in hard ground. The south drift on the 2760 level has been run and timbered 20 ft., making its total length 204 ft. from the station.

BULLION.—The incline winze is in a total depth of 200 ft. The material is a mixture of porphyry, clay and quartz of a very promising appearance. The water has retarded progress during the week, but has now decreased in flow, so that the work is easily handled.

SIERRA NEVADA.—The water in the incline has been lowered below the 2400 level. The work of opening the station on this level has been commenced. The progress will be very slow on account of the extreme heat, caused by the hot water flowing into the incline from different points between the 2300 and 2400 levels, and they not being able to obtain a sufficient supply of water to make the requisite pumping, and the same time work rapidly. The east drift on the 2200 level has been advanced 20 ft.; total distance, 185 ft. The face of this drift has become much softer since last report, and they have found it necessary to come back 20 ft. from the face and timber the ground.

HOT CREEK DISTRICT. RICH STRIKE.—*The Tybo Sun of Oct. 25th* says: A rich strike has been made in the old Dominion mine in Hot Creek district. The ore is of the same character as they formerly had in that mine—full of horn silver. The strike was made last Sunday, and it is showing up splendid as fast as it opened out. They have some 200 tons of ore on the dump that will assay from \$50 to \$250 per ton.

PARADISE DISTRICT. RICH ORE.—*The Silver State* says: Gen. R. M. Clarke called to-day on his return from the Paradise mines. He showed us a specimen of very silver ore from the Bullion mine, much of which is pure silver, and excels in beauty and richness anything of the kind we have ever seen from the mines in this or any part of the State.

MOUNT ROSE DISTRICT. IRONS.—A correspondent of the *Reporter* says of the Irons mine: The shaft is about 40 ft. deep; then the tunnel runs north about 120 ft., following the ledge all the way. This ledge is from 6 to 20 inches wide, the quartz being of a dirty, greasy gray. Character of metals—native, horn, ruby and chloride of silver, milling \$200 per ton. Cost of extraction, \$20 per ton. The next mine visited was the Big Prize. Here I noted a vein being sunk about 80 ft. west of the tunnel in very fine ore, and supposed to be the main ledge, while in the tunnel a shaft is being sunk on a two-ft. vein of good ore—native, horn, and ruby being generally diffused through the ledge or vein. The ore is free milling, and when any has been milled, has ranged from \$160 to \$200 per ton. The next, above or north of this, is the Bullion, one of the finest prospects in the district. The ledge is very large, requiring but few men to break down ore enough for the company's mill. This mine has been, and is, yielding some of the richest ore I ever beheld. The Mount Rose company's mine is also yielding some magnificent ore. This company is not trying to break down any ore, but simply drive.

CONTINUED ON PAGE 284.

Man and the Anthropoid Apes.

We must confess that the treatment of this subject is approached with misgivings that perhaps we may be guilty of disrespect to the remote ancestors which modern scientific theories have selected for us. Recent discoveries unearthed in Japan, which are claimed to slightly approach the "missing link" that once bridged over the gulf separating man from the apes, must be our excuse for presenting some ideas from Prof. Mivart in the *London Tablet*. When the gorilla was presented as our long-lost cousin, we did not feel particularly proud of the relationship, and our instincts strongly tempted us to try and disprove it altogether.

It was claimed that the gorilla possesses a special affinity to man, and if not our immediate ancestor, must at least be regarded as the chief visible bond between ourselves and the lower animals. A high honor for the gorilla, which we fear has never been fully appreciated by him. It certainly has not by his cousin, man. Whatever M. de Chaillu reported of his habits and tendencies was eagerly devoured, and even benevolent individuals formed plans for developing him into a member of civilized society, and bestowing upon him the right of suffrage. The head ideal of apes, he surpassed them all quite as much as man surpassed him. He was a vegetarian, so is man, a very creditable thing, and he showed his common sense by living in trees, which, considering the climate, was the best place to live in.

But the proud pre-eminence of the gorilla was disputed before long. Without any wish to derogate from his rightful claims, students of the ape tribe felt obliged to take facts as they found them. After close examination they could not put their hands upon their hearts and say that cousin gorilla does exhibit a greater number of structural characters like those of man than any other species in existence. They could not affirm on their conscience that they discovered in him those anatomical peculiarities which have special hereditary significances. Not even in external appearance was he more like to man than others of the ape tribe, and in this respect the chimpanzee and the orang might dispute the palm with him successfully. Like all the apes and half-apes, he has the great toe prehensile, and quite unlike man's, which forms the fulcrum in standing or walking. In a variety of anatomical particulars the orang, the Gibbons and the baboons agree with man more closely than does the gorilla. The Gibbon, again, is more human than the gorilla as to the preponderance of the skull's brain-case over the bony face, and in this respect the smaller American monkeys have the advantage over the Gibbons, and the squirrel monkey over man himself. As to a chin, the feature is wanting in a gorilla, but may be found somewhat developed in the siamang. Sometimes, as in the case of the slender little lemur (*loris*) there is, where we should least expect it, an approximation to part of the human structure beyond any that the gorilla can show. Indeed, so far as the skeleton is concerned resemblance to man is shared in different and unequal degrees by various species of the ape tribe, and no one kind is unquestionably much more human than any of the other.

But if we extend the comparison further—if we follow Prof. Mivart in every step of his minute investigation of the resemblances between other members of the order Primates and man the highest of them all—if we compare not only the bony structures, but the muscles, the brains, the nervous and other systems of the apes who bear respectively some faint likenesses of the human form and constitution, we shall be brought to the conclusion that the highly-favored ape from which man ought, so to speak, to have descended, must have had the voice of a long-armed ape, the beard and whiskers of a saki, the skull-dome of an American ape, the chin of a siamang, the wrist of the chimpanzee, the liver and stomach of the Gibbons, the ischium of a slender loris, and the blade-bone of a gorilla. In short, search as we may among the Primates, we fail to light upon the ape who is worthy to be regarded as the progenitor of man and who realizes in himself all that would be required to make him that "hairy quadruped, furnished with a tail and pointed ears, probably arboreal in its habits," to which Mr. Darwin pointed when tracing the descent of our species in his work published in 1871.

Nor does the difficulty end with our race. As we cannot find an ape *homunculus* from whom the human species may be supposed to have descended, so neither could we discover the probable ancestor of the orang or tarsier tribe. These animals have bodies quite as exceptional as ours. The little tarsier, indeed, is said to have even a more exceptional structure than man himself. And the peculiar forms of these animals show cross relations and complex dependencies of the most puzzling description. In whatever direction we might move, we should encounter a similar net-work of difficulties, if we endeavored to account for existing structures through the influence of inheritance and "natural selection."

Why may we not reject the principle of natural selection in the struggle for existence as sufficient to account for the presence of man on the earth, endowed with the glorious attributes of reason, conscience and free will, and explain it on purely scientific and philosophic grounds? In recognizing evolution as one of the pri-

mary laws of organic life, may we not account for the production of new forms of animals and plants, by special powers and tendencies in each organism, aided by natural selection and the survival of the fittest?

We do not by any means dispute the possibility of new and definite species emerging, under definite conditions, from known forms in the course of ages, but hold, on the contrary, that analogy drawn from the inorganic world is in favor of such latent potentialities. We admit the occasional appearance in organic structures of altogether new and abnormal features, nor would we deny the strange and startling transformations among the lower animals which have been observed of late years, such as the direct evolution of Rotifers and Nematoid worms, and mention as a fact, with which we have recently become acquainted, the sudden transformation of a large Mexican eel with external gills, called the *Axolotl*, into an animal not only of a different species but of a different genus. In this transformation the whole structure, and even the arrangement of the teeth, becomes completely transformed without our being able to discover what are the conditions of this marvelous metamorphosis.

The teaching of nature in regard to the genesis of species seems to be that similarity of structure frequently arises without the forms which resemble each other having any genetic affinity. It is rather to an internal cause—an innate tendency, an idiosyncrasy, a marvelous potentiality—than to surrounding conditions, that the origin of new specific forms is to be traced. The apes of the Old and New Worlds respectively appear to spring from different types, and what they have in common may be regarded as only parallel developments. Human beings, who in one organ or feature resemble one of the ape tribe, differ in other organs and features from others of the apes and half apes, the *Simiidae* and the *Cebidae*. It does not follow, therefore, that because we resemble this or that ape in this or that particular we therefore spring from one of his race, though "it is conceivable," as Professor Mivart has said, "that the physiological units of a living organism may be so influenced by surrounding conditions (organic and other) that the accumulation of these conditions may upset the previous rhythm of such units, producing modifications in them—a fresh chord in the harmony of nature—a new species!"

None of the gifts of man are found in the ape. Ages have not sufficed to develop in him the gift of speech, and perhaps no length of ages would or could develop it. It is mere irony to compare our bones and brains with those of baboons, when we have arts and sciences to show which seem to affiliate us to higher intelligences, such as many have called angels and gods. The surprising faculties which we possess seem not to be the result of our material organization, or of merely natural evolution, but to have been divinely implanted, and to have contributed greatly to the production and perfecting of this frame we tenant. It is impossible to deny that the body influences the formation of the mind, but it is no less certain that the mind in part modifies the body. "The organs of the brain," says Dr. George Harris, "are molded and influenced in their growth by the soul;" and Sir Matthew Hale, in his "Origination of Mankind," remarks that the body could not be reduced into that orderly frame in which it is constituted without the plastic and formative power of the soul.

There is in our mental constitution an action, a re-action and an inter-action unknown to the gorilla or his fellows in the woods and trees. We differ, therefore, from them in kind and not only in degree. We are among them but not of them. They are not our ancestors and they cannot be our kinsfolk. We have alliances with them, no doubt, in so far as we are organized structures; they have none with us in so far as we are rational, conscientious creatures, endowed with the gift of speech. We refuse to be presented in the court of nature as a relative of the gorilla or any of the apes. We are not anxious to diminish the gulf which separates us from the monkey tribe, either by raising them nearer to ourselves or by degrading our race nearer to a level with theirs. If the ascent of mankind from apes by a process of natural selection could be proved, we should be obliged by parity of reason to believe in the possibility of the inverse process of descent to the level of the beasts from whom we sprung; and the prospect of such a decline and degradation—even as remotely possible—is not one which we could entertain either with pride or pleasure. Yet it is a hypothesis much more easily demonstrated than that of evolution.

SCIENTIFIC COOKING ASSOCIATION.—In Berlin an association has been formed by housewives of the city. This society initiated last year various useful measures. Thus, it has opened a laboratory for examination of articles of food (now so much adulterated), as also, of utensils used in cooking. It is directed by a qualified chemist. The nature and quality of the objects analyzed at the Central Bureau are thus guaranteed. The chemist gives the members of the society a course of lectures in practical chemistry, and a cookery school has also been formed. Students are examined in the subjects of study; domestic servants who have remained a certain number of years (five) in one household (of a member of the society) are awarded with prizes. Last year 36 were thus rewarded. Another part of the society's operations consists in procuring places and work for servants with its members.

Lexington Oil Belt—Santa Clara County.

A late number of the *San Jose Mercury* contains an account of the above oil belt, its developments and history. It says: So many rumors of big things in oil have come to us from the Lexington oil region during the last 15 years, which afterwards proved to be largely of a fabulous character, that the public had crystallized into a condition of chronic doubt concerning the possibility of a pay strike in that section. Although it has been well known that oil existed here, yet but few people, especially after the first experiments at well-boring had been made, had any faith in the ultimate value of the district for oil mining.

Many of our older residents will remember the oil spring in what is known as Moody's gulch. This gulch is about two miles above Lexington, crossing the Santa Cruz road. The spring was located a few hundred yards above the road. Other and numerous indications of oil existed along a belt of country stretching across the hills and gulches in a southerly direction for a distance of five or six miles.

It was in 1865, we believe, when the first well, known as the McLeran well, was sunk, in Moody's gulch, near where once stood Moody's sawmills. This well was bored to the depth of some 400 or 500 feet, and a flow of about a barrel of oil a day procured. The well-boring tools were of a primitive order, and many difficulties were encountered from inexperience and imperfect machinery. Some of the principal tools were finally stuck in the well, where they remain to this day. A year later, over the summit, and about four miles from the McLeran well, the Fargo well was bored to the depth of about 400 feet, and about the same quantity of oil obtained as at the former. This was also abandoned as of no particular value. The same year Messrs. Pulsifer & Gould bored a well on the Griswold place, some two miles back of Lexington, to the depth, we believe, of about 500 feet. They found some oil and a considerable quantity of salt water. None of these wells were sunk deep enough. One or two other efforts were made at that time, and then the work was abandoned for 10 years, and until the organization of the Santa Clara Petroleum Co., when Col. Boyer took the matter in hand. With improved machinery and experienced assistants, the well, known as the Boyer well, was bored in the Moody gulch, to the depth of 940 feet.

At the depth of 700 feet a flow of from two to three barrels of oil was obtained, but no genuine oil rock was found, indicating that the well was at one side and near the true rock. For the past year this well has yielded and continues to yield about the quantity of oil named.

About a year ago the company became involved in new complications. Boyer was sold out by the Sheriff and disappeared from the scene, and new men came to the front. Among these were Charlie Felton, a man of indomitable pluck and a solid substratum of coin; and also R. C. McPherson, an experienced oil man from the Pennsylvania oil district, who was subsequently foremost in developing the Los Angeles oil district. It is to the sound judgment and true grit of Mr. McPherson, more perhaps than to any other person that the company has been kept steadily to its work for the last year and a half. He brought with him from Los Angeles some of his most experienced helpers, and imported from the East the best well-boring machinery to be had, and has pressed the work steadily forward to the present time.

Commencing a new well about 150 feet above the Boyer well, at a depth of a little over 700 feet the drill, a few days ago, penetrated the true oil sand rock. The result was most astonishing. So powerful was the escaping gas that the oil was thrown to the height of 100 feet, drenching the derrick and buildings, and flowing down the canyon. It is estimated that at least 100 barrels of oil was wasted before the well could be secured. Since then *she* (oil men always speak of a well as of the feminine gender, and often apply pet names to her), has acted like a "Little Daisy." The flow has been fully 60 barrels per day, of the finest green oil, of from 46 to 47 standard gravity, while the standard of the best Pennsylvania wells is only 45 grade. As the best evidence of the genuineness of this strike we may state that during the brief period it has been in operation the company has shipped some 300 barrels of oil by the Narrow Gauge railroad. The oil at present is piped down the gulch to the turnpike, and thence hauled to Alma station, about a mile distant. It is the intention soon to pipe it through to the railroad, and eventually, probably, to San Jose.

About 200 feet up the gulch from the main well work is progressing for another well, and will be pushed forward speedily to completion. The company is also preparing to bore a well, over the range, on the Taylor place. Near the latter place work is progressing rapidly on what is known as the Whiteside well, under the same company. The altitude here is about 300 feet above that of Moody gulch. The well is now down nearly 800 feet, and is in most encouraging rock. It is near here that the O. L. Crandell and Hy Morrill claim is located, one of the largest and most promising prospects in the oil belt. (And here we take pleasure in adding parenthetically that Mr. Crandell has stood in from the first, in the oil business, and never lost faith in the ultimate results. The prospect is now luminous that a rich reward will

gladden the remainder of his days, which we hope may be many).

A number of new rigs will be prepared as soon as practicable, and in a short time from six to eight wells will be going down at once. In fact, the certain success already attained will so stimulate enterprise in this direction, that we may reasonably expect the time is near at hand when our oil regions will swarm with busy laborers, and millions he added to the wealth of our county and State.

Historical Sun-Darkenings.

The near approach of the total eclipse of the sun may afford cause for the selection of a short article on the above subject from the pen of J. R. Hind, in *Nature*. Mr. Hind says: In 536, 567 and 626 we find mention of long periods of diminished sunlight. Schnurrer records that in 793, a year after the Saracens had been driven back beyond the Pyrenees, consequent on their defeat at Tours, "the sun darkened in an alarming manner on August 19th; there appeared to be no eclipse by the moon, but rather an interruption from some meteoric substance." There was an eclipse of the sun, annular, but nearly total, on this morning of August 14th. It is mentioned in a Saxon chronicle, which tells us "the sun's disk was like a black shield." The near coincidence of dates suggests in this case a connection between the darkness and the eclipse. In 934, according to a Portuguese historian, the sun lost its ordinary light for several months, and this is followed by the doubtful statement that an opening in the sky seemed to take place, with many flashes of lightning, and the full blaze of sunshine was suddenly restored. In 1091, on September 29th, not 21st, as given in some of the translations of Humboldt's "Cosmos," Schnurrer relates that there was a darkening of the sun which lasted three hours, after which it had a peculiar color, which occasioned great alarm. In another place we read: "Fuit eclipsis Solis II. Kal. Octob. fere tres horas: Sol circa meridiem dire nigrescebat." There was no visible eclipse at this time, and the November eclipse was central only in the southern parts of this earth. A century later, or in June, 1191, according to Schnurrer, the sun was again darkened, with certain attendant effects upon nature. Here the cause is easily found; on June 23d there was a total eclipse, in which the moon's shadow traversed the continent of Europe from Holland to the Crimea; the eclipse was total in this country between the coasts of Cumberland and Yorkshire. Erman refers to a sun-darkening on February 12th, 1106, which was accompanied by meteors, and we read in cometographies that on the 4th, or according to others, on the 5th of February, in that year, a star was seen, from the third to the ninth hour of the day, which was distant from the sun "only a foot and a half." Matthew Paris and Matthew of Westminster term this star a comet, and we may take it to have been the same which, later in the same month, was observed in China under the sign Pisces, and which at one time was supposed to have been identical with the great comet of 1680. This body, however, would not appear to have been sufficiently near the earth as, even on the assumption of a denser constitution than usual with comets, to account for a diminution of the solar rays by its intervention. On the last day of February, 1206, according to a Spanish writer, there was complete darkness for six hours. In 1241, "five months after the Mongol battle of Leignitz," the sun was so obscured, and the darkness became so great, that the stars were seen at the ninth hour about Michaelmas. In this case, again, the darkness referred to was undoubtedly due to the total eclipse on October 6th, of which Prof. Schiaparelli has collected a full account from the Italian writers. Lastly, in 1547, from April 23-25, Kepler relates on the authority of Gemma, "the sun appeared as though suffused with blood, and many stars were visible at noonday." Schnurrer thought this phenomenon was what the Germans call a "Hohenrauch," notwithstanding the visibility of stars.

From the above brief summary of what have been considered abnormal sun-darkenings, we see that in several cases the diminution of light has been due to the ordinary effects of a total eclipse, while it is clear that there are no grounds in the historical evidence for any prediction of a period of darkness. The nervous in these matters, and it would really appear that such exist, may take consolation therefrom.

EDUCATIONAL CRAMMING.—Prof. Huxley, speaking of the high pressure or "cramming" system in the schools, says that the children so taught are "conceited all the forenoon of life and stupid all its afternoon," and, also, that "their faculties are worn out by the strain put upon their callow brains, and they are demoralized by worthless childish triumphs before the real work of life begins. I have no compassion for sloth, but youth has more need for intellectual rest than age, and the cheerfulness, the tenacity of purpose, the power of work which make many a successful man what he is, must often be placed to the credit, not of his hours of industry, but to that of his hours of idleness in boyhood."

MR. S. H. SCUDDER'S "Catalogue of Scientific Works" is now completed and has been printed by the Directors of Harvard University Library. It is a book of 300 pages and 50 pages of index. The entries in this catalogue represent over 70,000 volumes.

The "Live Yankee" of Nevada County.

The Nevada City *Transcript*, speaking of the mining business of this county, alleges that about 20 quartz claims are now in successful operation in the district, all of which, as they attain depth, furnish new indications of permanency. The Live Yankee and Perseverance have recently added another big paying property to the list, which promises to be one of the best, if not the leading one, in the section. These locations are about one mile south of Nevada City, on the Half-Mile House road leading to Grass Valley, and near its junction with the Rough-and-Ready road. They are in slate formation, and in the same mineral belt as the Providence, Wyoming, Merrifield, Nevada City, Thomas and Pittsburg, lying near the center of the group. Some 20 years ago the surface over and near them was sliced, and fortunes were made from the rich deposits of quartz gold. For some time as high as \$300 per day for two men was taken out, and for months not less than \$50. It being very evident that the gold came from some rich ledges near by, many shafts were sunk in searching for the fountain head. In time the Live Yankee was discovered. It being a blind ledge, or in other words not showing on the surface, and as no rich specimens were found at first, it was left idle for many years.

The Perseverance was prospected a little at different places on the surface, and was found to be a large formation. The fact that the gold in it was fine, as well as the quartz being considerably mixed with the slate, was very much against it at that early day. No depth was sunk, and it remained undisturbed, from the reason that early miners, as a rule, passed by all ledges that had been tried by those who went before them.

In March, 1877, the Live Yankee was located by C. W. Beedle, James Stevens and R. E. Robinson, although some of the same company had done a small amount of work on it previous to that time. Some very rich specimens were taken out by them and exhibited in town for several days. The dirt near the ledge was also very rich, some of it paying as high as \$10 to the pan. The ledge was found to be from one to two feet wide, and some of the ore milled has paid over \$100 per ton. The locators put up a windlass and sunk 40 feet, to water.

Shortly after the location of the Live Yankee, some quartz that showed considerable gold was found on the cappings of the Perseverance, and the ledge was located for 1,500 linear feet, the same distance as that on the Live Yankee. The latter ledge intersects the Perseverance at a point about 200 feet west of the Grass Valley road, and leaves it at an angle of 40°, running in an easterly direction. Between these two are three or more ledges. As the former were located with 300 feet of ground on either side of each, it included them, and they were all consolidated under the name of the Live Yankee mining company's claim.

The locators had worked the Perseverance to a depth of 40 or 45 feet, to water, taking out a quantity of ore which for the first 20 feet in depth paid \$9 per ton, and below that \$18.

In August, 1878, the property was bonded for the term of one year and two months to Fred. Jones, formerly of Grass Valley, who was so long identified with the Empire mining company, and was about one of the first engaged in quartz mining at that place. Pumping and hoisting machinery was placed on the mine by him, and a new shaft sunk for the purpose of testing the ledge below water level. At the depth of 93 feet drifts were run and considerable ore taken out and crushed. It showed free gold and great deal of sulphurets. The heavy sulphuret ore was worked separate at the Omaha mill for a test, and yielded 40% of sulphurets, paying \$96 per ton. For the shafts and drifts to that depth the ore all averaged \$34 per ton. At the depth of 123 feet, drifts were run, and considerable ore taken out and milled. The last 110 tons worked paid over \$40 per ton, and yielded 15½ tons of sulphurets.

It is acknowledged by the best miners that no mine opened here has shown such a fine quality of ore and so much of an improvement with the depth worked as this. The ledge in the bottom drifts varies from two to six feet in thickness and contains a large percentage of high-grade sulphurets. The locality and the advantages surrounding the property add value to it. Custom mills and sulphuret works are within 1,200 feet. It is less than one mile from the Narrow Gauge railroad depot, and less than half a mile from Town Talk station. The main-traveled stage road from Nevada City to Grass Valley crosses the ledge within 25 feet of the principal working shaft. The surface is quite smooth, and the ledge crosses 30 acres of thickly-timbered land belong to the same owners.

The V Flume Company's lumber and wood yard and office is but one-fourth of a mile distant on a raise of ground, making lumber, wood and water convenient at all seasons of the year. But one shaft is required to work all the ledges.

A few days since this property was sold by Mr. Jones to J. T. Bradley, Esq., of Oakland, who intends to shortly erect heavy pumping and hoisting machinery, and sink a deep, perpendicular three-compartment shaft. Cages and all other modern improvements are to be used, and the mine is to be worked on a very extensive scale. Mr. Jones, who has developed the mine thus far, will remain in charge.

USEFUL INFORMATION.

Toughened Glass.

A paper on the above subject was submitted to the Iron and Steel Institute at Liverpool, by Mr. Wood, in which it was stated that the glass is molded into various forms to suit the different requirements, the cooling of the glass being so regulated that the radiation from each point of the surface corresponds to the thickness of the glass, thus enabling the casting to be equally affected throughout when undergoing the tempering or hardening process. The regulation of the radiation or absorption of the heat in the thicker parts of the casting is effected by using iron hollow molds and by circulating cold water or cold air at those points where the glass is thickest, so that the casting cools equally in every part. The mode of toughening the glass is both curious and instructive, affording, as it does, a complete contrast to that of steel. The glass is heated to a high temperature, and then plunged into a bath of cold oil or other liquid, the result being that it becomes converted from its own characteristic brittleness to the remarkable tough fibrous material known as toughened or tempered glass. But to produce the desired effect and obtain the full advantages of the toughening process upon articles of great strength and thickness, Mr. Siemens found that the hardening or tempering could be effected in the molds themselves—first, by carefully protecting the glass from coming into direct contact with the mold, to prevent chilling the surface of the glass; and, secondly, by the use of hollow molds for maintaining a uniform temperature all over the casting during the hardening. The temper is modified in these thick castings by passing them through an annealing oven. The molds are chiefly protected by layers of wire gauze, perforated metal, or plaster of Paris, varying in layers or thickness according to the rapidity and energy required in tempering and the nature and composition of the glass, this energy being increased at the thick parts of the casting before alluded to by the circulation of cold water or air through the cast-iron hollow molds. So far as experience has shown, all kinds of glass are equally affected by the process. The time might come, Mr. Wood thought, when we should not only see glass sleepers, but glass tools and implements, eaves, troughing, spouting, furniture, and many other things. The average transverse resistance of the glass sleepers laid on the North Metropolitan trams was found, supported at 30 inches, to be about five tons.

[The increasing yield of petroleum oil on this coast will lead to the production of large supplies of paraffine, one of the products of petroleum, and in connection with the use of toughened glass, it may be well to say that this paraffine, when freed from the concomitant acids of refining, possesses a greater tensile strength than ordinary glass. Hence there is room for experiment in the way of hardening it, the ease with which it can be manipulated being in its favor.—EDS. PRESS.]

MINERAL SOAP.—About three years ago there was discovered, near Elko, a deposit of a peculiar character, which upon being tested proved to possess remarkable detergent qualities. Analysis of the material showed that it was composed of many of the constituents used in the manufacture of the soap of commerce. Within the past six months the "soap mine" has been worked by an incorporated company and the product utilized in the manufacture of mercantile soap. We yesterday received a call from E. A. Littlefield, of the Elko Post, who left some samples of this useful article, which proves upon test to be all that the manufacturers claim for it. The company are now making and shipping from Elko about a ton of soap per day, but this will be increased to ten tons within a few weeks. Its cost is about the same as that of inferior brands of soap, which it will supersede in due course of time.—Nevada State Journal.

INDIAN STEEL.—The remarkable metal known as Wootz, or Indian steel, is now imitated with considerable success in some of the workshops of Europe, the process being as follows: Small pieces of very good forged iron or steel are put in a crucible and covered with charcoal; air is carefully excluded, and the mass exposed to heat until it turns dark gray—carbureted of iron; this is easily pulverized, and in this state it is mixed with alumina and subjected for a long time to a white heat in a crucible, when it becomes white and brittle. If 3 to 1-12 of this white mixture is melted with some good steel, a very good imitation of Indian steel is said to be the result. Commercially speaking, the genuine raw steel, or wootz, comes in three forms, namely, in hullet-shaped pieces of a certain weight as they cool in the pots, and which comes from Calcutta; in cakes of 2½ pounds, from Bombay; and in cylindrical rods of about the same weight, from Golconda.

ARTIFICIAL ASPHALT.—Dingler's Journal says V. L. Dagusan heats cold tar in a boiler until all the water is evaporated, then adds finely pulverized marble, or limestone that has previously been burned, stirring in 5% of iron oxide, silicate of potash, and gypsum, mixing the whole thoroughly.

LUMINOUS POWDERS.—Two patents have been recently taken out in England for phosphorescent powders. One of the patentees states, in his specification, that his object is to obtain and utilize at night-time the light absorbed during the daytime from sunlight or an artificial light, either by employing the powders after exposure, or by augmenting their brilliancy by means of electricity. The powders are made by taking 100 parts by weight of carbonate of lime, and phosphate of lime produced by the calcination of sea shells; secondly, 100 parts of lime rendered chemically pure by calcination, and after the above are mixed, 25 parts of calcined sea salt are added, then 25% to 50% of the whole mass of sulphur incorporated therewith by sublimation, 3% to 7% of coloring matter in a powdered form composed of mono-sulphuret of calcium, barium, strontium, uranium, magnesium, aluminum, or other minerals or substances, producing the same appearances, i. e., which become luminous in the dark. The other patentee says of his phosphorescent substance, that he prefers calcined oyster shells combined with sulphur by exposure to sufficient heat, or a paste formed of neutral arseniate of baryta and gum tragacanth or sulphide of strontia, or sulphide of barium in combination with a small percentage of magnesia. For rendering walls or surfaces for advertising or other purposes luminous in the dark, they are coated with an adhesive substance. The phosphorescent substance is then spread over the surface, and then coated with transparent varnish or other transparent substance.—Scientific American.

PRESERVATIVE WRAPPING AND PACKING PAPER.—Mr. John F. Rodgers, of Philadelphia, has patented a preservative wrapping and packing paper, for protecting cloths, furs, etc., from mildew and ravages of moths and other insects. The paper used is made from woolen and cotton rags and manila rope or manila paper. This paper is saturated with a mixture of 70 parts, by measure, of the oil remaining from the distillation of coal-tar naphtha by live steam with 5 parts crude carboxylic acid containing at least 50% of phenols, 20 parts of thin coal tar heated to about 160° F., and 5 parts of refined petroleum. After saturation, the paper is passed through squeezers and over hot rollers for the purpose of drying. When cool, it is cut into sheets as desired, and the drying completed in the atmosphere. The paper thus treated is used for packing woolen clothing, cloths, furs, carpets, and all material likely to be injured by moths, mice, or vermin, and will also to a great extent, it is claimed, prevent cotton material from mildew.

TO MAKE HOLES IN HARD STEEL.—Holes can be made in hard steel by the application of nitric acid. True, they will not be very perfect, but cases may occur where such an operation will be very convenient. The process is as follows: Cover the steel plate, where you wish the hole, with a thick layer of melted wax; when cold, make a hole in the wax of the size you want the hole in the plate, then put on one or more drops of strong nitric acid, leave it on for some time, wash off with water, and if not eaten through apply other drops of the same liquid, and continue this until the plate is perforated.

GOOD HEALTH.

Sleep.

In a work on "Sleep and Sleeplessness," by J. M. Granville, it is claimed that sleep is a rhythmic function of life. It is performed by the nervous system, either through a single center or by the several centers connected with various parts or organs of the body, from the supreme cerebral centers which control the immediate apparatus of intentional thought to the ganglia that regulate the work of the viscera. I believe the sympathetic system plays a conspicuous part in the production of the phenomenon, and this is why the due performance of the function is so readily prevented as it is by disorderly action in almost any part of the body, even when there is no sensation of pain or of uneasiness at the seat of the disturbance. People who do not sleep well and regularly are peculiarly liable to functional disorders; and, conversely, those who are subject to the anomalous maladies and symptoms too often set down to fancy, but actually existing and traceable with care to some special ganglion of the sympathetic system (for example, uneasiness in the "pit of the stomach," or aching pain in the lower lumbar region of the spine) are disturbed or disorderly sleepers. Sleep is a nerve estate, whether the part sleeping be the brain or certain parts of the organ, the muscular system or viscera. The modifications which take place in the vessel supplying the organ or system that sleeps are the effects or consequences, instead of the causes of its condition.

The author devotes a chapter to the subject of going to sleep, and considers here the use of narcotics for the purpose of inducing it, observing that "the state they produce is not sleep, but a condition of narcotism that counterfeits sleep," adding, "When a man says, 'I want a quiet night; I cannot obtain it by going to sleep, or I am afraid to trust to the chances of natural rest, so I will poison myself a little, just enough

to make me unconscious or slightly paralyze my nerve centers, not enough to kill.' If this fact should be kept clearly before the mind, the reckless use of drugs which produce a state that mocks sleep, would be limited." The state of inaction which is brought about by natural sleep is very different from that which is produced by paralysis of any degree. The following remarks are important:

Habit greatly helps the performance of the initial act, and the cultivation of a habit of going to sleep in a particular way, at a particular time, will do more to procure regular and healthy sleep than any other artifice. The formation of the habit is, in fact, the creation or development of a special center, or combination, in the nervous system, which will henceforward produce sleep as a natural rhythmic process. If this were more generally recognized, persons who suffer from sleeplessness of the sort which consists in simply being "unable to go to sleep," would set themselves resolutely to form such a habit. It is necessary that the training should be explicit, and include attention to details. It is not very important what a person does with the intention of going to sleep, but he should do precisely the same thing, in the same way, at the same time and under as nearly as possible the same conditions, night after night for a considerable period, say three or four weeks at least. The result will amply reward the effort.

ANTI-FAT MINERAL WATER.—While surveying in the mountains northeast of Anaheim last year, Major Wm. P. Reynolds encountered a man who had worked for him in former years. He failed to recognize him, however, until the stranger explained who he was. It was no wonder the Major failed to identify his old acquaintance, for he was now a man of about 200 pounds weight, whereas he weighed 340 pounds when in the Major's employ. The secret of his reduced avoirdupois was freely given. A short distance up the mountain from where his house stood was a spring, the waters of which contained some mineral anti-fat. Did the Major want to lose some of the superfluous flesh which encumbered him? He did; he drank the water, and in 10 days his weight had been reduced 25 pounds. He continued drinking the water, until from weighing 212 pounds, he was reduced to 170 pounds, his present weight. This was accomplished without any violent action on the part of the water; it seemed to go about its business quietly and efficaciously. Major Reynolds will obtain water from the spring, and he will forward it to the Smithsonian Institute at Washington for analysis. The spring is about 16 miles from Anaheim, easily accessible, and if analysis establishes the fact that there is nothing to be apprehended from using the water, there will be numerous obese persons avail themselves of the opportunity to try nature's remedy. There is still another spring in the mountains possessing qualities as peculiar as the one mentioned. It was discovered one hot day by a couple of young men from Anaheim, who were on a prospecting tour. The water from the spring had flowed into a kind of natural reservoir, and it looked so cool and inviting that the young men doffed their clothes and took a bath. A few minutes after they came out their skin and hair took a reddish tinge, and they became like unto the aboriginal red men. It gradually wore off, however, and in a few days their color was a natural dirty brown.—Anaheim Gazette.

CAUSE OF STAMMERING.—M. Chervin has of late drawn attention to the frequency of stammering in the south of France, where from 12 to 13 cases are noted for every 1,000, while in the eastern departments the proportion is only 1 for every 1,000. It has been assumed that the defect was in many cases simulated to avoid the conscription, but according to Abbe Petitot there are two districts in the Bouches-du-Rhône where all the inhabitants (15,000), stammer. This he ascribes to long-continued intermarriages among the communities, and to a consequent degeneracy of the race; and M. Chervin is of opinion that meningitis, induced by the great solar heat, which occasions so high an infantile mortality in this region, may possibly, when not fatal, leave an exceptionally great tendency to stammer.

ANTISEPTIC FOR INFECTIOUS DISEASES.—Prof. Klebs, of Prague, announces that the benzoate of soda is the best antiseptic in all infectious diseases. It acts, as the experiments of the author show, very powerfully. It is claimed that a daily dose of from 30 to 50 grammes to a full-grown man will render the poison of diphtheria inoperative. The benzoate is prepared by dissolving crystallized benzoic acid in water, neutralizing at a slight heat with a solution of caustic soda, drying and then allowing the solution to crystallize over sulphuric acid under a bell-glass. Large doses do not appear to be absolutely necessary. Good results may be obtained by the daily administration of about 12 grammes.

NASAL RESPIRATION AND HEARING.—The influence of nasal respiration on the ear is illustrated by Mr. George Catlin in his history of "The North American Indians." Among 2,000-3,000 Indians he found not one who was deaf or breathless through the mouth, except three or four deaf mutes; and in the memory of the chiefs of 150 tribes not one case of deafness could be remembered to have occurred. This is explained by the mother always closing the mouth of the child whenever it attempted to breathe through it.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Prof. Church on the
 Comstock Lode, 273-281. The Week, The Govern-
 ment and the Miners; Light and Heat of the Sun, 280.
 Hart & Nicholson's Gang Plow; The Bodis Nocturnal;
 Some Words to Investors; Can't be Dons, 281. Patents
 and Inventions, 285.

ILLUSTRATIONS.—Substituted Masses in Mineral
 Veins, 273. Hart & Nicholson's Improved Gang Plow,
 281.

CORRESPONDENCE.—Suggestions for the Land
 Commission; The Comstock Mining District, Nevada, 274.
 MECHANICAL PROGRESS.—Removing Boiler
 Incrustations; Improvements in Colliery Winding Gear;
 The Great Pan-Maker and His Wife; Instrument to De-
 tect Color Blindness; An Induction Balance; Electric
 Jewelry; Manipulation of Steel; Cactus Mattresses; A
 Chance for Inventors, 276.

SCIENTIFIC PROGRESS.—Forests and Meteor-
 ology; Electricity in Flowers; Blood of the Lobster; The
 Coloring of Autumn Leaves; The Camphor Edibles; In-
 combustible and Impermeable Wood; Animal Electricity;
 American Scientific Association; Fire-Damp in Mines;
 Igniting Tinder, 275.

MINING STOCK MARKET.—Sales at the San
 Francisco, California and Pacific Stock Boards. Notices
 of Assessments, Meetings and Dividends, 276-7.
 MINING SUMMARY from the various counties of
 California, Nevada, Arizona, Colorado, Idaho and
 Oregon, 277-284.

USEFUL INFORMATION.—Toughened Glass;
 Mineral Soap; Indian Steel; Artificial Asphalt; Luminous
 Powders; Preservative Wrapping and Packing Paper;
 To Make Holes in Hard Steel, 279.

GOOD HEALTH.—Sleep; Anti-Fat Mineral Water;
 Cause of Stammering; Antiseptic for Infectious Diseases;
 Nasal Respiration and Hearing, 279.

MINERALS.—Sun Dance Among the Sioux,
 274. Man and the Anthropoid Apes; Scientific Cook-
 ing Associations; Lexington Oil Belt—Santa Clara Co.;
 Historical Sun-Darkening, 278. The "Live Yankee"
 of Nevada County, 279.

 Postponement—Diana M. Co.
 To Mining Men, S. W. Howland, S. F.

The Week.

The elements of prosperity evidenced in the continued and steady increase of prices of iron, lead and quicksilver, and the firing up of heretofore silent furnaces in the East, indicate a return of better times, not only to the East but to this coast. The events of the week are not of any startling magnitude. The sounds of preparations for a period of activity during the coming winter are heard in every town and hamlet on this coast, and, in fact, in the whole Rocky Mountain region. Men are already talking about what they intend to do, what improvements they are about to make, and the look of care and evil anticipation has evaporated, giving place to the smile of pleasant anticipations. The prospectors are still busy, coming in with their usual "specimens" from new finds, as our Mining Summary will show.

The Indian troubles of Colorado and New Mexico, if not entirely settled, have at least lost their paralyzing features of war and blood. The feeling of safety has infused new life into the veins of the miners in the savage-infested regions, and all are preparing for a successful development of mines.

The Land Commission is bringing out a variety of opinions as to the changes that should be made in the mining law, and surely it seems as if the opinions of those who have had long experience in the needs of a mining community, would prevail over the interested ones of selfishness and avarice.

The unfortunate occurrence of the week was the disastrous fire at Colfax, on last Tuesday, in which a large portion of the town was laid in ashes. The loss is estimated at about \$75,000. The people of Colfax have the sympathies of all for their affliction, which is all the heavier as it comes at the beginning of what is prophesied will be a hard winter, so far as temperature is concerned.

Taking the events of the week together, we may say that good influences are prevailing, and that it will be our pleasant task to record greater prosperity a week hence.

The Government and the Miner.

The advent of Mr. King upon the Comstock, and the announcement that the study of our great mining districts is to be resumed, and now carried out on a scale much more comprehensive than ever before, is a circumstance of the first importance to every man engaged in the metallic industries. There is no doubt that the Government can do much to foster any enterprise by undertaking to publish, for the benefit of all, the facts that are usually hidden in the knowledge of a few successful men. But in undertaking this work, for the benefit of the miner, the Government is often severely criticised.

What has the Government to do with private mines? is the question. But it is too late to ask it. For many years the agricultural interests and the fishery interests of the country have been carefully looked after by the general Government, and at a cost which is far in excess of anything that the important mining industry has had expended upon it. We have just risen from the payment of five and a half million dollars for the privilege of fishing in Canadian waters, when we could buy the fish much more cheaply. Every day we use manufactured articles which we are able to make, because this Government has been committed for half a century to a policy of protecting the constructive industries of the country. With such examples before us it is evidently long past the time when an inquiry of what business the Government has in private matters can have any force. A settled policy, and a wise one, of doing for each great department of labor that which can be done without furthering individual monopolies, has long ruled our country, and the mining men are entitled to their share of its benefits.

Before the war the Government engaged in the work of prospecting the ground for a trans-continental railway, and when the enterprise was finally undertaken, by private parties, the fruits of this great work obtained by repeated expeditions at immense cost, were not only turned over to the promoters but where not even reckoned among the gifts. They were looked upon as common property which any one could take. After the war the system of public surveys grew to a wonderful extent and included a careful and costly study of the geological formation, the beasts, birds, plants and herbs of the great West. Several surveying parties followed out this work on parallel lines, producing rivalry, confusion and repetition. The field they operated in had two great industries—mining and agriculture. One of them was already carefully fostered by an important branch of the Government service, but the other had been and continued to be treated with neglect. For fifteen years surveying parties have roamed over our mountains covered with men who are laboring to develop the mines, and who sorely need all the help they can get, but with two exceptions this immense activity in the cause of science, costing the people in some years nearly a million dollars, has never done anything for the miner. The Fortieth Parallel Survey produced the most important contribution to mining industry ever made in America, and in 1877 Lieut. Wheeler, then in charge of the surveys west of the one hundredth meridian, prepared for a similar work, by sending Prof. Church to the Comstock to continue the exploration of that important example of American lodes. With those two exceptions the costly surveying parties have seldom risen above puerility in their treatment of the most important scientific and practical question in their field of action.

This state of things now promises to come to an end, for we believe that Mr. King owes his appointment as Director of the scientific surveys to the certainty that he would give the mines their due attention. With the able men his corps contains, there is no doubt that at length the important and obscure problems of vein geology will receive some explanation. Mining has continued in some form, and even in a highly advanced state, for centuries, and yet the character and structure of veins are still mysteries.

This state of things cannot continue in the face of observation and publication. It is publicity and discussion that has raised metallurgy from its degraded condition of half a century ago to its present strong and thriving state, and the work done on our mineral veins will be felt in the furthest corners of the earth. Our mining field is peculiarly well fitted for the work. Out of all the blunders that have obscured the study of veins, the fact that they have, or that a large class of them have, intimate relations with the occurrence of erupted rocks, stands clear and strong and gains positiveness constantly. Our country contains the greatest extent of igneous rocks known in the world, and in the multiplicity of examples that are offered it is almost certain that important laws may be discerned.

The work of King, Hague and Emmons on the Fortieth Parallel Survey, and the work of Church on the Comstock, now just appearing, are forerunners of a series of which the best hopes may be cherished, both for American miners and for the world of science.

The Cabinet at Washington have decided that the War Department shall deal directly with the refractory Utas.

Light and Heat of the Sun.

It is very singular that modern science should be guilty of inconsistencies in relation to the connection between the geological structure of the earth and the influence thereon of the solar light and heat. In the great anxiety to dispute the Mosaic account of creation, it has been demonstrated, on the one hand, that it would require 20,000,000 years to bring about the present structural features of the earth, and that during that period the sun had been assisting in the formation by the exercise of its powerful influence. On the other hand, it was demonstrated that the sun was an enormous incandescent body, requiring an inconceivable amount of fuel to keep up its heat and light. There was no conspiracy of opinion upon these two points, no comparison of notes. Observations proceeded until infinity has been reached, to-wit, an eternity of geological strata in the earth, and an infinite perpetual combustion occurring in the sun, so intense, indeed, that if the earth were to be suddenly cast into it, the effect would be less than if a single drop of water were thrown into a blast furnace.

Having disposed of the Mosaic theory, one of the questions now put to science is: "Whence does the sun, if incandescent, derive its supply of fuel?" The ever-ready reply is, "dead planets, comets, meteors." Without wishing to be impertinent, we would suggest that, if this combustion of dead planets, etc., has been going on for so many millions of years, and is still going on, why has not the supply given out, or why can not astronomers see this rush of hodie into the sun?

The sun of our system, without mentioning the multitude of suns of other systems, has certainly had time and opportunity to consume everything within its limits, from Mercury to Neptune. Yet there is no diminution of the body of the sun, and, consequently, no diminution of the fuel supply. If we agree that the sun is fed with meteors, etc., we must, in accordance with its immense requirements, provide such a shower of bodies upon it as would obscure our vision of space. A small annual fall of meteors cannot keep up the enormous combustion demonstrated to exist in the sun. It is claimed that the bodies injected into the sun are invisible, principally because they are not hot enough to be seen. But the moon is a dead-cold planet, perfectly visible by reason of its reflected light, and why should not the solar fuel flying through space be visible for the same reason? If the cosmical substances flying through space are too small individually to reflect light, the enormous aggregate should certainly present at least a nebulous appearance. This problem of solar heat and light is not a satisfactory one to solve. According to Dr. Henry Raymond, there are at the present time four different explanations of the production of sun light and sun heat, viz.: (1.) Combustion of cosmical substances falling into sun; (2.) arrest of motion of such cosmical substances; (3.) contraction of the solar mass; (4.) dissociation of compound bodies in sun's substance. He holds that the first hypothesis, that of "combustion," is virtually given up by scientists on account of its insuperable difficulties. The fuel problem is too intricate for the finite mind. The second, the so-called mechanical hypothesis, is held in greatest favor by scientists to-day, as best accounting for the phenomena, or as being least vulnerable to objections. This hypothesis presupposes the presence in space of an incalculable supply of ponderous masses, all roving loosely and by chance until, falling under the influence of the sun, they are drawn thereto with such momentum that the concussion gives rise to inconceivable light and heat. But Dr. Rogers believes that such existence of ponderable matter, away from the influences of gravity, moving about in the universe, and assumed to follow the attraction of the nearest stellar system, can hardly be credited by philosophic minds. The supposition that old, useless worlds, comets, meteors, etc., are attracted to the sun to be utilized for the production of its light and heat, is contrary to every principle of reason and sound philosophy. The inevitable enlargement of the sun's dimensions, which would occur from the accretions resulting from this method, would also prove fatal to this hypothesis. An exact knowledge of the sun for centuries has not in the slightest degree disclosed a change of radius in the earth's orbit—a necessary consequence of any change in the sun's bulk. The third hypothesis, "the contraction of the solar mass," implying a progressive diminution of that body, finds the same objections which lie against its progressive augmentation. The fourth, "the dissociation of compound bodies in the sun's substance," depends upon the process of combustion, and is, therefore, open to the objections already mentioned. Each of the foregoing hypotheses stands in direct opposition to the inexorable law of conservation of force. According to the decree of that law, whatever is received by the earth from the sun, an equivalent for the same must again be returned from the earth to the sun to the uttermost fraction. No hypothesis based upon any other foundation can stand. Dr. Roger's theory of the cause of solar light is a magnetic one. He believes that the sun and earth are gigantic fountains of magnetic influence, continually acting and reacting upon each other, and that this view gives to

the phenomena of light and heat their clearest and fullest interpretations.

Prof. Benjamin Peirce, of Cambridge, venerable in years and profound in research, supposes that the solar system is surrounded by meteors so numerous that their total weight exceeds by 100 or 1,000 times the mass of the sun. Being dark, they are invisible, but we may suppose them to form an irregular envelope or series of envelopes; since we find such a constitution frequent in the stellar nebulae, in which countless minor masses surround glowing centers of attraction. He also says: The assumption of the extreme cold of space, though based on a mathematical theorem with some claims to probability, is not impregnable; and if we admit that the meteors have some heat when they start on their way to the sun, the estimate of their product in heat on arrival must be increased. The great jets of glowing hydrogen gas which Prof. Young has so faithfully observed issuing from the sun's surface to enormous heights, can scarcely be accounted for on any theory of mere condensations in the solar mass. They are great outbursts, such as might result on a smaller scale from violent explosions; they fly outward with enormous velocity; they arise from the vast chasms of sun-spots. It is not difficult to believe that they are the upward splash when some great meteor dashes downward into the gaseous body of the sun.

To still further provide for the theory of a meteoric envelope, Prof. Peirce claims that these meteors are not hot enough to be visible, even if they were of efficient size. Yet he argues that they have some heat when they start on their way to the sun, and increase that heat in space, which, he says, need not be extremely cold. If this be true, then they must become hot enough to be visible if of proper size, and that they are large enough is plain from the assertion that the hydrogen jets which issue from the sun's surface to the height of 150,000 miles, are caused by the splash of some great meteor into the gaseous body of the sun.

But all this is sheer supposition, and may be declared improbable from the fact that the enormous quantity of matter in the shape of meteors, required to feed the sun, could not be in motion without being visible. The few meteoric showers annually observed are nothing in quantity. Again, if it be true, as Prof. Peirce alleges, that the space outside the solar system is largely tenanted by viewless meteors, which form the chief supply of the sun, what power compels them to seek the sun as a combusive center? If it be the attraction of the sun, why, then, does this attraction exercise an influence upon one meteor and not upon all? The truth is, if the power of the sun attracted one meteor it would all, and the result would be to increase the bulk of the sun 100 or 1,000 times, for he says this meteoric matter is that much greater than the mass of the sun; and if there be any power of attraction which regulate the descent of these bodies upon the sun, it must possess a greater power than the sun, and hence would draw the meteor into its own constitution and away from the sun. It would require an unnecessary stretch of the imagination to consider the confines of the solar system to consist of an envelope of meteors, each one awaiting its turn to be precipitated into the sun—an envelope of inert matter, movable only in one direction, viz: toward the sun, and then only at stated intervals. Such a mass of developed matter, remaining immovably fixed in space, would suggest the idea that perhaps the Hindoo cosmogony of Vishnu seated upon a turtle and holding up the earth might not be wholly erroneous. It is true that there exists in space unformed matter as great in quantity as the immensity of space is infinite; but the formation of meteors, as needed for the sun's combustion, would be at the expense of this matter, and the rushing together of the particles toward and around the nucleus of every meteor would be attended with heat and light, the latter of which would be visible to the naked eye, and a tremendous apparition through a telescope—a condition of things which does not exist so far as present human experience is concerned. It would seem possible to explain the mystery of the sun as a source of light and heat by a more comprehensive system and one more in accordance with the logical conceptions of the stability of the universe; but we reserve further remarks upon the subject for our next issue.

WE DON'T KNOW.—An exchange having its headquarters in the carbonate belt of Colorado proposes a conundrum which we give up. It says: "If I am using my muscle and small capital in sinking a shaft, say two feet a day, in hope of striking mineral, why should Mr. Long-purse be permitted to come along with his bank account, and, putting in two or three shifts, run a hole down within 50 feet of me at the rate of 10 feet to my one, and on striking mineral before me, proceed to survey in my little patch of ground, shaft and all?" The fate of the prospector seems to be that of every man who is struggling for existence, namely, inability to realize any benefits from the results of his weary toil. Pioneers leave a name behind them, and are cited as examples of self-sacrifice, etc.; but so far as legal protection of their rights is concerned, there seems to be room for substantial changes in the law.

A FIFTY-FOOT vein of cinnabar is reported discovered in Fremont county, Colorado. This is the first quicksilver discovered in that State.

Prof. Church on the Comstock Lode.

(CONTINUED FROM PAGE 273.)

it. He claims that this discovery is of great importance, for it can prevent needless expenditure in prospecting the flat parts of the ground where ore never has been found, and in this way reduce the costs of exploration.

The fact that ore occurs only in the steep parts of the lode is explained by the supposition that the hanging wall has moved on the foot wall, and this was occasioned, according to our author, by the eruption of trachyte which loaded the hanging wall with so great a weight as to press it down. In this movement the flat parts of the lode would be pressed more strongly together, and it is a curious fact that the well-known hardness of the barren quartz which occupies these flat portions receives an explanation in this theory. It has been pressed to a firm mass. In fact through all the work the author's effort has been to weave the observed effects together so as to form their own theory. While the flat portions would be pressed together, the seams of the steeper parts would be opened and new depositions of quartz would be formed by substitution.

The quartz bodies lying in this highly inclined position contain paying ore, while those on the flat dips do not, though they sometimes hold a little gold and silver. On this account Prof. Church divides the filling of the Comstock in two periods, the siliceous and the metalliferous. The first followed the andesite and the second followed the trachyte.

If this discovery is sustained both in the Comstock and in other lodes formed in a similar way, it will have great importance as affording a clue to the date at which the silver ores of the Pacific slope were deposited. Hitherto nothing has been known on this point. The rocks which enclose them are of various ages, and all that can be said of the date at which they were impregnated is that it may have been quite recent for all of the formations, for there is no reason to suppose that it was contemporaneous with the rocks that hold the deposits. Some curious facts and speculations are given upon the origin of vein quartz, and the certainty that if it all came at one time and in solution, there must have been vast floods of water, and of metalliferous water, poured out at the time in question.

It is gratifying to find that a careful explorer rises from the examination of our greatest metallic lode, with the most hopeful views of its future. At present there is a most unmistakable impression abroad that the Comstock is practically exhausted, but Prof. Church seems to have become a geological "hull" on the prospects of the lode. Take, for instance, some of the impressions he received, as follows:

That the origin of the ore is as deep as the origin of the eruptive rocks andesite and trachyte, or many thousand feet below the present depth of the mines.

That there is no good reason known for asserting that the process of substitution and ore formation is confined to the neighborhood of the surface. More probably it continues through the whole depth of the propylite, or, perhaps, 12,000 feet, and may be richer below than above.

That the presence of the barren zone, in which most of the mines have been working for years, is due merely to the existence of a flat dip there and that ore is likely to make as soon as this is passed, in any part of the lode, and the requisite steepness, or contrast of flat and steep dips in alternation is reached.

That the Comstock lode may not be the only productive lode in that region. There are other lines of quartz deposition, both west and east of it, as large as their great neighbor, and though they have never produced rich ore, that is no reason for saying that they never will. The ground that has been explored in them may be a barren zone, like that in the Comstock now, and if their exploration is continued intelligently better results may be obtained. The Professor says we must turn our eyes from the Comstock lode to the Comstock system of lodes, and that the latter may afford a varied mining industry for a great length of time.

Indeed, our author goes so far as to say that even the Bullion mine, which has never produced ore, may do so at some time, and this opinion, which may meet with incredulity in many quarters, he rests upon the fact that nothing in the ground of that mine indicates any impossibility of receiving ore. The Divide, on which it lies, may spread out and diminish in depth and better conditions come in.

From all these examples it may be seen that the author has very strong impressions of the permanence and value of our mining resources, and in these times of doubt and hesitation, his favorable impressions will be very acceptable.

He found that the propylite, and even the lode itself, contains fragments of tree trunks, and from this fact he concludes that the rocks were not poured out pell-mell, but in successive active periods, with long pauses between them.

The form of the bonanzas and the position of the ore are illustrated in six colored plates, which give the details of the Con. Virginia, California, Crown Point, Belcher and Justice ore bodies. Both horizontal and vertical sections are given, and they are made up in a way to show how extensive were the author's facilities for studying his ground. In addition, there are thirteen engravings, to illustrate more exactly various sections and positions of the bonanzas.

We have touched only one part of the au-

thor's subject, which also covers the formation of the country rock, the questions of heat, ventilation and drainage, bullion statistics, etc. All of these problems have unusual importance from the fact that the Comstock is only probably one of a great number of similarly-formed lodes. The lessons that are to be learned in its extensive openings are also valid elsewhere.

Hart & Nicholson's Gang Plow.

We illustrate herewith an improvement in gang plows, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Rueben Hart and Milford P. Nicholson, of Santa Maria, Santa Barbara county. The bearing wheels of the plow are made of large diameter, and the axle which unites them is either cranked or bent upward; or the axle may be made short, and secured to each end of an axle bed, which may be cut away below, as shown, the object being to provide a space into which the plow beam, C D, can be raised in lifting the plows. These beams are united at the front, and support the pole, and they diverge as they extend backward, one being shorter than the other, as shown in the engraving.

The plows are secured by standards to the plank, F, extending between the beams. This plank is slotted at the points where the bolts secure it to the beams, so that its ends may be moved forward or back, so as to adjust the plows to or from the land. The forward ends of the beams pass above a strap under the axle bed, as shown. Stout rods extend from this strap up through the axle bed at each side of this space, and tubes are secured to the sides of the beams, so as to slide upon these rods and guide the plow beams in their vertical movement.

The upper ends of the rods, projecting above the axle bed, form supports for the operating

HART & NICHOLSON'S IMPROVED GANG PLOW.

lever. On each side of the plow beams, at the front ends, are secured eyes, and links unite these eyes with the ends of the levers, L. The long arms of these two levers are brought together at some distance behind the axle and upon the right, so that the single end may be united with the lever, M, by a link. This lever, M, has its rear end supported by a standard in the rear end of the plow beam, D, and serves as a fulcrum for the lever. The front end of the lever has a catch to engage with the rack-bar, P.

By the use of this compound lever perfect control of the plow is gained, and the driver on the seat readily lifts the plow beams. The operating lever, M, is placed at one side of the machine; but by means of the forked or double levers, L, with their double bearings and lifting links, the weight is distributed so as to fall equally upon each wheel.

The peculiar action of the compound lever and standard is not only to raise the front end of the plow beams, but also to raise the rear end of the beam, D. As the rear end of the beam, C, is supported on the caster wheel and the plows extend in a diagonal line from near this front to the rear end of the beam, D, it produces a tendency of this rear end of D to drag downward as the plows nearest to it enter the ground, and this combination of levers and standard counteracts this tendency.

In order to raise and lower the rear end of the beams, C, the standard of the caster wheel is fitted to move in a sleeve upon the side of the beam, and its upper end is connected with the lever, U, by a swivel shackle, or link, as shown. The rear end of the lever is curved, so that by the operation of the lever, the rear plows will be lifted more or less. This lever extends forward and has a rack and catch to hold it in any position.

The construction described has several advantages over the ordinary sulky or gang plows, among which may be enumerated the method of operating the front and rear ends of the plow-beams independently of each other, each end in turn serving as the fulcrum or point about which the other moves. This admits of the plow being employed to great advantage in lay-

ing out land, for which purpose the front end will be raised and the rear end depressed. This causes the rear plow alone to take the land, thus cutting a boundary furrow. By raising the rear end and depressing the front, the front plows alone may be used to finish up the last of a plowing.

When both ends are raised, the plows will be entirely clear of the ground, and as the caster wheel moves freely with its swivel standard, the machine may move around in either direction, swinging about a center between the wheels, so that the turning may always be accomplished upon solid ground. The arrangement of the levers produces great power, so that the plows may be easily handled by the driver from his seat. The team may be harnessed to the plow, and a load of seed be placed on the frame and hauled to the field, dispensing with the use of a wagon. Further information concerning this invention may be gained by addressing the inventors at the above address.

The Bodie Noondays.

In some editorial remarks in our last issue on the Bodie mines, we took occasion to speak of the exceptionally good management of the several claims that make up the Standard and Noonday groups. What we said of the latter it gratifies us to find confirmed by so good an authority as Joseph Wasson, who, besides possessing peculiar fitness, has enjoyed peculiar opportunities for forming intelligent and correct opinions in regard to these mines, concerning some of which he holds the following language: "The original Sandhank croppings, upon which the South Noonday is located, are identical in character with those of both the Noondays. The South Noonday joins the Queen Bee ground on the south, and the Stanford company on the north. The trend of the dividing ridge of the whole mineral belt,

Some Words to Investors.

The New York Mining Record of Oct. 18th, takes occasion to make a few remarks upon the above subject, incited thereto by a table recently published in the New York Times, showing the market price of certain railway stocks and bonds on the 7th of Oct., this year and last, respectively. The Times table shows in the aggregate an appreciation in the stock valuation of some 19 roads, over that of 1878, of \$138,540,000, with a further appreciation for the same period on the valuation of the bonds of nine other roads, of \$8,617,000.

The tables were originally prepared to show, apparently, that the business recovery of the country was entirely too healthy, and affords an illustration of the tendency, in flush times in the East, to employ speculatively the accumulated capital of our great money centers in stock-gambling, rather than in fostering those industrial enterprises upon which really depend the prosperity of the country, namely, agriculture and mining, including metallurgy.

The Record remarks that nearly all of the railroad stocks are not only of no more value intrinsically to-day than they were 12 months ago, but absolutely they are without any substantial value. As the Times puts it, "the earth has bubbles as the water hath, and these are of them." While this is very rough language about the pet speculative material of the East, to wit, railroads, it is nevertheless true. Railroad securities to a great extent possess the certainty which may be urged of an ordinary game of draw poker, viz., luck. Within the past few years railway stocks to the amount of over one thousand million of dollars have become extinct, the last holder caught with stock losing his money.

The Record finds relief from this purely speculative, lottery ticket business of railway stocks in investments in mining enterprises, and we heartily coincide with the remarks of the Record, when the investment is properly made, as it can and should be. It says: The business done in stocks (railway stocks), intrinsically so valueless, adds nothing to the wealth of the country. Not so, in great part, with the money advanced in mining enterprises; it is employed in developing the subterranean riches of the land, and adding outright to the money material of the commercial world. Nor is this all. Every new mining field opened causes railways to be built that otherwise would have had no reason for being; it creates a demand for costly machinery, the construction of which gives employment to our skilled mechanics; it widens and enlarges the field for a hundred business occupations that otherwise might be stifled by the competition incidental to a more contracted territorial area.

Can't be Done.

An "aggrieved stockholder" in the Mining Record has been trying to invest his spare cash in mining stocks, taking the representations of newspapers as his criterion of value, and finds trouble and vexation. He says he invests in certain mines which are considered good by one newspaper, and finds by another that he has made a losing investment, and learns to his horror "that he had placed his savings literally in a hole in the ground." Now he thinks some newspapers are contemptible for decrying every young and undeveloped mining property, especially the belittling and decrying of a great and immensely successful enterprise like the celebrated Eureka Con., and wants that sort of thing stopped. The individual who invests in stocks must to a certain extent "go it blind." It is said that the course of true love "never runs smooth," and we are quite sure that stock speculation is not smooth sailing. The investor pays his money and takes his choice. How he is to be helped by the newspapers withdrawing opposition to some mines, is not apparent to the naked eye. If every journal should combine and praise all mines as immensely rich, or immensely worthless, they wouldn't put one cent's worth of metal in the mine or take it away if there. Mines are very much like men: if they have any merits they will be found out and utilized fast enough. There may be an object in puffing a mine, as well as in decrying it. What that object is forms one of the intricacies of the stock business which would require a volume to explain. The business looks simple enough, but unfortunately it happens that the simplicity of the thing is not so much in the business as in the over-credulous investor. Beware of the g f t-hearing Greeks.

Five counties in California contain quicksilver mines. During the past three years the aggregate production has been, in flasks: Napa county, Redington mine, 25,493; Lake county, Sulphur Banks, 30,849; Great Western mine, 14,266; Sonoma county, Oakland, 4,687; Fresno county, New Idria, 17,846; Santa Clara county, Guadalupe, 18,952; New Almaden, 56,483. A flask of quicksilver contains 76½ pounds.

A glass manufactory in Hanover, Germany, makes glass which is a close imitation of marble, and tables and floor tiles which are pronounced preferable to marble on account of their extreme hardness.

NATIONAL IRON WORKS.—The new iron works of Cantrell & Marshutz, on the corner of Main and Howard streets, are nearly ready to start up and it is expected the first melt will be made by Monday or Tuesday. We shall give a description of these new works in our next issue.

It is said that Lesseps and his engineers having adopted the theory that the Israelites crossed near Lake Timsh, the Abhe Meigne, editor of Les Mondes, appeals "to the whole Christian world" to subscribe the requisite funds to enable "the relics of the army overcome by Almighty himself" to be brought to light.

 611 and 613 Front Street, San Francisco

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free. Address.

DEWEY & CO.,
 202 Sansome St., N. E. Cor. Pine,
 San Francisco.

PRACTICAL
Lessons in Assaying and Testing.

Use of Acids and Blow-pipe. Useful Information for Miners, Millmen, Prospectors and youths, on reasonable terms, by the lesson or full course. DR. FOLSOM, Assayer, 608 Market Street, San Francisco.

BEFORE TESTED AND ASSAYED.

REDDING, July 12th, 1879.
 Messrs. Dewey & Co.—Gentlemen:—Have received my letters patent for the bar roller to-day. I am very much obliged to you for your prompt service, and will recommend you to all who may want your assistance.
 I remain yours, etc., Geo. M. PINE.

Winchester Repeating Rifle,

MODEL 1873.

The Strength of All its Parts,

The Simplicity of its Construction,

The Rapidity of its Fire,

The Power and Accuracy of its Discharge,

The Impossibility of Accident in Loading,

Commend it to the attention of all who use a Rifle, either for Hunting, Defense, or Target Shooting.

The San Francisco Agency is now fully supplied with all the various kinds and styles of Arms manufactured by the Winchester Repeating Arms Company, to wit:

Round barrels, plain and set, 24 inch—blued. Octagon barrel, plain, 24 inch—blued. Octagon barrel, set, 24, 26, 28, 30 inch—blued. Octagon barrel, set extra heavy, 24, 26, 28, 30 inch—blued. Octagon barrel, set, 24, 26, 28, 30—extra finished, case hardened and check stocks. Octagon barrel, set extra heavy, 24, 26, 28, 30 inch—extra finished—C. H. & C. S. Octagon barrel, set, 24, 26, 28, 30 inch—beautifully finished—C. H. & C. S., known as "One of One Thousand." Octagon barrel, set, gold, silver and nickel plated and engraved. Carabines blued, also gold, silver and nickel plated. Military rifle muskets, model 1873. Rifles, muskets and carbines, model 1866. RELOADING TOOLS, PRIMERS AND PARTS OF ARMS.

A heavy stock of Cartridges Manufactured by the W. R. A. Co., for all kinds of Rifles and Pistols, constantly on hand and warranted the best in the market.

Sole Agent for Dupont's Mining, Blasting, Cannon, and Celebrated Brands of Sporting Powder.

SANDERSON BROS. & CO'S

BEST REFINED CAST-STEEL.

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock, and for sale at

21 and 23 Fremont Street, S. F., - H. D. Morris, Agent.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 20th, 1860, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

Metallurgy and Ores.**Nevada Metallurgical Works,**

No. 23 STEVENSON STREET,
Near First and Market Streets.

Ores worked by any process.

Ores sampled.

ASSAYING in all its branches.

Analysis of Ores, Minerals, Waters, etc.

WORKING TESTS MADE.

Plans furnished for the most suitable process for working Ores.

Special attention paid to Examinations of Mines; plans and reports furnished.

PIONEER REDUCTION WORKS.

G. F. DEETKEN - - - Manager.
Channel Street, off foot of Fourth, San Francisco, Cal.

Highest price paid for Sulphurets, Arsenurets, Tellurides and Gold Ores generally.

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending hocket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

Photo Relief & Wood Engraving

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SCIENTIFIC PRESS ENGRAVING CO.,

No. 202 Sansome St., S. F.

In consequence of spurious imitations of

ing ahead and sorting that which comes out of a 4x6 tunnel. Character of mineral—argentic, galena, antimonial, and chlorides of silver. The Paradise mine is yielding good ore, and plenty of it, with two or three meadows' run on this dump.

PEAVINE DISTRICT.

WASHOE COUNTY.—This *Reno Evening Gazette*, speaking of a visit to the mines of this district, says: The Manzanola mine lies about four miles north of Reno and half a mile west of the Long valley road. The croppings are immense at the south end of the claim, where they surmount a very high ridge. A canyon crosses the north end of it, and Mr. Scott has made an open cutting just at its lowest point, which shows up a very promising ledge. There are some disturbances consequent upon the breaking up of the ground in some of nature's frolics, but the east wall is of very handsome blue clay mixed with sulphurates. This ledge has never been crossed, so no one can tell anything about it, but one thing is certain, the rock is full of rich sulphurates which will concentrate perfectly, and judging from the immense croppings, which are of the same character, there is no doubt of a mine there.

PIOCHE DISTRICT.

DAY MINE.—*Record*, Oct. 25: The Superintendent, A. S. Gould, in his last official letter, says: We are steadily taking out ore and sending it to the Hillside furnace, as per your order. I am obliged to considerably increase our force of men, a great deal of outside work being necessary in preparing for winter, especially upon roads to the ore-house and ore-dumps. We are driving down with one incline, from the lower tunnel level, as fast as possible, measuring to-day a depth of 34 ft. The bottom is all in ore of a moderate grade. The changes, however, are so frequent that it is difficult to determine the average quality. Thus far, this drift is in the north drift, and here we commenced stoping to-day.

ARIZONA.

HUACHUCA.—*Tucson Star*, Oct. 23: An old mine has been discovered at the south end of the Huachuca mountains, near the Sonora line, which has created quite an excitement, owing to the high assays which have been got out of the debris of the old dump piles. It has been extensively worked at one time, and was doubtless an enterprise of the old Jesuit fathers of the past century. The high assays give the discoverers great assurance that they have a bonanza.

THE SANTA CATALINAS.—Parties in from the east side of the Santa Catalinas report the mines developing finely. Some very rich ore has been found near the American Flag mine, and also in Reed's camp. Assays of the former go as high as \$1,300 per ton. These camps are well situated for wood, water and grass, and accessible from Tucson by good roads.

COLORADO.

FAIRPLAY MINES.—A correspondent from Alma in the *Denver Tribune* of recent date says: Several big strikes have lately been made in this camp. One was made by J. R. Lampkin on Buckskin hills, between the Phillips and Fanny Barret mines. He was attracted by a fissure plainly to be seen on the walls of the cliff, which, on striking with his pick, exposed very fine galena, which for 6 ft, clear across the streak, rock and all on the surface gave a result of 41 ounces silver per ton. This lead was staked, located, and called the *Earnest*. Work was immediately commenced on it, and in a few days a streak of pay, 24 in wide, was developed, showing very rich ore in native and ruby silver, and black sulphurates. A mill run was then had from it in Leadville, which ran 297½ ounces. At the present time they are down on it 5 or 6 ft, and have just struck the first contact at the bottom of the limestone. They are now taking out native silver, ruby silver, black sulphurates, free gold, native copper, and very fine carbonate of lead. The contact is plain to be seen, and can be traced through the Rock Island and adjoining claims to the Fanny Barret. The lower part of the contact is about 10 ft below where they are now working, and it is thought by experts that when it is reached very rich ore will be found. Another strike was made at the west side of Mount Bross. W. J. Mullen & Co., of Colorado Springs, have made a new strike, which assays higher than anything yet struck in the State, assaying from 5,855 to 23,358 ounces of silver to the ton. It is called the *Beck* lode, and is situated on the west slope of Mount Bross, some distance above timber line, and is thought to be the extension of the Dolly Varden. Carbonates have been struck in the last few days at the timber line on Mount Bross, which assay 60 ounces silver per ton. Captain Grose's find near the Dolly Varden is looking well. The largest strike in the State, however, has been made recently of sand carbonates above timber line four miles to the northwest of the old town of Montgomery on the Pacific slope. Five tons of the ore is reported to have brought its owners \$9,000 in Leadville. Several new and rich finds have been made at the head of Pennsylvania gulch, and also on Sacramento. The Sacramento mine, in the latter place, shows an immense body of high grade ore, running 500 to 600 ounces silver per ton.

IDAHO.

YANKEE FORK ITEMS.—Speaking of the low grade ore belt the Yankee Fork *Herald* of Oct. 18 says: Messrs. Sweeney & Parks, on Tuesday last, located a 30-ft vein of quartz in the hills two miles below town and on the south side of the river. Assays show the extremely low grade of \$12 per ton in gold and several dollars in silver. There is a vast belt of this low grade ore on that side of the river, and extending through to the high mountains some miles to the south. The top ore assays all the way from \$8 to \$20 per ton in gold with traces of silver. Owing to the inferiority of the quartz compared with that of other sections of the Yankee Fork district, little attention has been given it, and no ledge has been prospected beyond the depth of a few feet.

Some very fine carbonate ore is being shipped from the Beardsley. This ore averages about 140 ounces in silver and 35¢ lead.

We learn that our friend Ned Rotch, who prospected in these parts several weeks during the past summer, has recently struck the richest silver ledge yet found in the Saw Tooth district. The ledge carries a small vein of black sulphurates nearly half silver, assaying as high as \$15,000. Are we yet prospecting pards, Ned?

OREGON.

MONUMENTAL MINE.—A correspondent of the *Grant Co. News*, speaking of this mine, says: The mill building is about 200 yards west of the mine, is 100x150 ft, and nearly 75 ft high. The mill will work about 30 tons of quartz per 24 hours, requiring 9 men. Describing the mine, the writer says: In traveling a distance of 700 feet we were shown 16 different veins or ledges of quartz, each from 4 in. to 3 ft in width, all dipping towards No. 3, and apparently coming together at no very great distance below. No. 3 consists of a group of ledges occupying a space of perhaps 40 ft, and in most mining camps would be called a 40-ft ledge. From appearances, one should say that the most work has been done on No. 13, or No. 14, and is a chute for the ore and a manway for the workmen to go up and down. This shaft is timbered all the way from top to bottom, with heavy timbers, framed in after the fashion of making log houses, leaving a space inside of about 24 by 6 ft, with a partition in the middle to protect the manway from the falling ore in the chute. After examining all of the different drifts on a level with the main tunnel, we were conducted up the manway of the air shaft to the 200-ft level on No. 13, where we found the vein of quartz varying in width from 8 to 30 inches, and rich in ruby and antimonial silver. Leaving this level we ascended to the 100-ft level, where we were shown along

the level for a distance of 150 north, to the bottom of the old prospecting shaft of the discoverers, and at a depth of 100 ft from the surface.

ITEMS.—*Jacksonville Sentinel*: Geo. W. Elliott & Co. have an arastra running on the quartz taken from their ledge near Willow Springs. The vein they are on prospects very rich, and they anticipate realizing a profit from their prospecting operations with their present appliances. The gold obtained is free from sulphates or other base metals and easily saved.

BIO NUOOR.—Messrs. C. Y. Miller and James Eaton, who have been at work mining on Elliott creek, a tributary of Big Applegate, recently took out of their claim a nugget of pure gold weighing \$120. They have taken out many smaller pieces weighing from an ounce to \$5, besides a considerable amount of fine gold. Reames Bros. purchased the large nugget.

Mineral Veins and the Electric Current

The Grass Valley *Union* of October 25th says: "Mr. Phillips, who claims for his electric machine the merit of indicating the course of mineral-bearing veins, and their relative size and character, has lately been experimenting upon the Iron-Clad mine, below Rough and Ready. He found the shaft to have been sunk upon a stringer of good size, but not upon the main ledge. The instrument indicated the lay of the main ledge, which was some distance from the stringer, and from following this indication the main ledge has been found cropping out strongly in a ravine, where it had not before been discovered, and showing a width of from ten to twelve feet. Miners generally do not place faith in the discovery of ledges by such means, but Mr. Phillips has unlimited faith in the efficacy of this machine, claiming that it is just as practicable to use electricity in discovering the existence and course of blind ledges as utilizing it above ground or under water in transmitting telegraphic intelligence. Prof. Edison, we believe, advanced similar ideas when he visited the Comstock. The possibilities of science are very great, and experiences will yet demonstrate whether this is one of them."

We give the above to illustrate the modern tendency of science to experiment upon old ideas with recent mechanical appliances.

Fifty years ago (in 1830), the relation between metallic veins and the electric current was discussed in the *Institut de France* (seance du 18 Octobre), and it was announced that William Fox, from observations made in the mines of Cornwall, had discovered that their veins exerted a manifest action upon the magnetic needle. *The direction of the currents being in accord with the inclination of the vein, and the axis of the magnetic poles.* "La direction des courants était en rapport avec l'inclinaison des filons et avec l'axe des poles magnetiques."

Debreyne, in his "Theorie de la Cosmogonie et de la Geologie," in 1856, upon this subject of the formation of metallic veins (page 245), says: "I attribute them (the veins) to the action of the telluric and even helical currents which traverse the terrestrial beds, and there incessantly deposit or modify certain metallic substances. Basing this hypothesis upon the belief that the earth is similar to a galvanic battery which transports elementary molecules in the same manner as the Voltaic pile."

"Nous les attribuons a l'action des courants telluriques et meme heliques, qui, traversant les couches terrestres, y déposent ou y modifient incessamment certaines substances metalliques et transportent des molecules elementaires absolument comme les courants de la pile Voltaïque."

We might cite many other instances of the connection between metalliferous veins and the electric current, but we have said enough to show that the idea is not new. Perhaps if the same amount of investigation were bestowed upon this theory of the formation of mineral veins, more might be accomplished than through other speculations.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Christy, October 22d, \$5,315.00; Martin White, October 19th, \$4,550.90; Bodie Con., October 28th, \$16,500.00; Northern Belle, October 25th, \$4,912.66; Alexander, October 24th, \$4,626.90; Standard Con., October 27th, \$20,022.45; Hillside, October 29th, \$4,000.00; Martin White, October 26th, \$6,197.85.

THE "ATLAS" MINING COMPANY listed their stock on the San Francisco Board yesterday. We hope to see the "Atlas" prove a bonanza, the same as Leeds and the great Ontario that has paid its millions in dividends and never was assessed. Utah mines rank high both here and in the East, as both rich and productive, equal to any other mines on this coast.—*Stock Report*, Oct. 24th.

SETTLERS on the Los Bolsas Rancho, Los Angeles county, are peaceably submitting to the legal proceedings taken to eject them.

The British and German governments have favorably received the recent circular of Secretary Evarts in regard to Mormonism.

The revenue of Russia last year amounted to 625,972,000 roubles, and the expenditures aggregated 1,033,972,000 roubles.

The captive women and children of the White River Agency have been delivered in safety to Special Agent Adams.

Some Leadville Items.

A correspondent in the *Denver Tribune*, thinks the interest in Leadville is increasing. With regard to the mines of the great carbonate camp he says:

At no time in its history has there been more satisfactory progress made in opening and developing the mines than is being made now. The older and better known mines not only keep up their well-earned reputation, but are constantly increasing in value as the work progresses. Fryer hill still maintains its ascendancy, as is evidenced from the rich discoveries recently made in the Little Pittsburg, Little Chief, Robert E. Lee, Duncan and others.

The former, after sinking a shaft 80 feet below the first deposit, has come upon a rich bed of high-grade ore, equal to any that has formerly been taken from this valuable property. This discovery seems to upset the prevailing theory among experts of the existence of but one stratum of carbonates in the Leadville deposits. Others, who have held to the opposite doctrine, that where there was one deposit there was good reason for believing that others existed below, regard the Pittsburg lower stratum as a separate and distinct deposit from the one above—a stratum, the existence of which cannot be explained, either upon the "break" or falling theories, so persistently adhered to by some of the older mining experts and geologists.

The Little Chief immediately adjoining the latter, has also gone down upon a large body of very excellent mineral, which fully sustains the reputation this valuable mine has long enjoyed, of being one of the richest in the whole camp. This mine has probably paid its fortunate owners more than the full amount expended in its purchase, and can still exhibit some of the finest bodies of ore to be found in any mine in the world.

A few hundred feet to the west of the last-named mines are the Robert E. Lee, the latest wonder, the Duncan, Matchless and Climax. These have recently proved to be equally as valuable as those found earlier upon this remarkable hill. The Robert E. Lee has, within the past few days, turned out ore of surprising richness, mill runs from which have run from 1,000 to 15,000 ounces in silver to the ton. The statement made by one of the principal assayers yesterday, that this ore carried from 60% to 95% in silver, shows the wonderful richness of this last bonanza. The claim is a very small one when compared to the full extent allowed by law, but the high-grade ore fully compensates for the loss of territory. One or two acres of such mineral will suffice to make millionsaires all those fortunate enough to possess an interest in this claim. The Lee is owned by Colorado Springs parties.

The Duncan, Matchless and Climax, immediately adjoining, are also valuable mines, which are growing richer every day. In fact, Fryer hill seems to be turning out better even than its most sanguine friends dared predict. Scarcely a mine on this hill has been worked for profit alone, most of them being opened simply for development, and yet there are croakers who seem to take a particular delight in predicting the early decay of Leadville and its wonderful mines. If there were no other properties in the district, save those on Fryer hill, this camp would be the liveliest mining camp in the whole county for some time to come. But there are other localities which are rich in promise, some of which even have shown rich mineral and in seemingly inexhaustible bodies.

Carbonate hill, which promised to fairly eclipse the older sites, has made no important developments since the rich strike in the Morning Star. Several claims on the western side of this hill, below the Carbonate, Crescent and Pendery, have suspended operations after working bravely through the summer months, hunting after the deposits which were believed to exist below the Pendery. A visit to the hill recently showed most of its claims idle, and in some cases the machinery had been removed. The Welden, which has a shaft down 230 feet and upwards, has failed to find mineral in quantities sufficient to pay. The Gem of Leadville, still lower down the hill, is seriously troubled with water; in fact, to such an extent as to stop all further operations pending the arrival of hoisting machinery. The St. Mary's, Big Dutchman, Lazy Bill, Machuckinock, Cosmopolitan, Pocahontas and some others have stopped work entirely.

On Bruce hill the excitement still continues, and rich ore is being taken in large quantities from the Highland Chief, Colorado Prince, Miner Boy, Lowland Chief and others. A stamp mill is about to be erected near the Colorado Prince. The ore from this mine is rich in gold, as well as valuable for its silver.

The town itself is as busy to-day as at any time since the mining excitement first began. Buildings are going up in all parts of the town, some of which would be a credit to any section of the country. The new Opera House is being closed in rapidly, and will no doubt be ready for occupancy about the middle of the present month. Another theater has just been put up at the head of Harrison avenue, on Chestnut street, to be opened as soon as completed, or about the 10th instant. Some Boston parties recently purchased four lots on Harrison avenue, above the Clarendon Hotel upon which they are erecting a large two-story building, to be rented for business purposes and offices. Nearly all the rooms are already rented, although the building will not be completed for several weeks yet. There is great demand for dwelling-houses,

for which high rents are offered. This demand indicates a change in the character of the permanent population of the city. Last winter there were but few females in the town, whereas now quite as many ladies can be seen upon the streets as in most towns and cities of the same number of inhabitants.

The gas works are completed and mains laid through all the principal streets. Probably before November 1st the streets will be lighted with gas and a metropolitan aspect thus be given the magic city.

Decisions of Commissioner of Patents.

Ex-parte Sullivan & Burke.

Decided August 26, 1879.

This name, "Bob Ingersoll," associated with the representation of the bust and head of a man, is registrable as a trade-mark for cigars, Mr. Ingersoll having filed his consent, in writing, to this registration.

Interlocutory Appeal—Trade-Mark.

Application of Sullivan & Burke, filed June 4, 1879. Mr. Thomas S. Sprague for appellants; Paine, Commissioner.

The applicants seek to register, as a trade-mark for cigars, the words "Bob Ingersoll," associated with the representation of the bust and head of a man. The examiner declines to register this trade-mark, on the ground that the applicants have no right to appropriate the name of Mr. Ingersoll for such a purpose. Mr. Ingersoll has objected this objection by filing his consent, in writing, to the registration.

The trade-mark will be duly registered.

Burgess vs. Wetmore—Magazine Fire-Arms. Decided August 26, 1879.

1. As against a prior applicant, who had reduced the invention to practice before his application was filed, it is necessary for a subsequent applicant to show, not only priority of conception and diligence in the prosecution of the invention, but also a lawful reduction to practice.

2. A concession of priority is, under the rules, binding upon the parties to the concession, and also upon all the parties to the interference. But the rule goes no farther. It permits no party, by a concession, to fix the date of an invention of another party as against a third party to the interference. It renders no statement of foreign matter, introduced into the concession, legal evidence against, except the persons who make them.

3. The reduction of an invention to practice by a person who is not the inventor nor the agent of the inventor, even though he may have derived his knowledge of the invention from him, is not equivalent to a reduction to practice by the inventor himself. The law accords the patent to the latter applicant, who connects, by due diligence, a prior conception, not with a reduction to practice by some one else, but with a reduction to practice by himself or his agent.

News in Brief.

MIDHAT PASHA has resigned the Governorship of Syria.

STANDARD silver dollars coined to date, 44,453,850.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manufac-
ture of Screens. Mill owners using Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.
32 Fremont Street, San Francisco.

Books for Miners and Millmen

KUSTEL'S ROASTING OF GOLD AND SILVER ORES, and
the extraction of their respective metals without quicksilver.
Illustrated, 142 pages. 1870. A valuable and carefully
written work. Postpaid, \$2.50. Published and sold by
Dewey & Co., S. F.KUSTEL'S CONCENTRATION OF ORES (of all kinds), in-
cluding the Chlorination Process for gold-bearing sulphurets,
arsenides, and gold and silver ores generally, with 120 litho-
graphic diagrams. 1867. This work is unequalled by any
other published embracing the subjects treated. Post-paid,
\$7.50. Printed and sold by Dewey & Co., S. F.PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS
COMPANION, comprising a practical exposition of the various
departments of exploration, mining, engineering, assaying
and metallurgy. 472 pages and 83 illustrations. A most
valuable and comprehensive book of reference to prospectors
and practical miners. Post-paid, \$10.50. Sold by Dewey
& Co., S. F.A RON'S TREATISE ON WORKING SILVER ORES.—Illustrated, 114 pages. 1878. A useful and practical work, free
from technicalities and extremely serviceable for miners' use.
Post-paid, \$2. Published and sold by Dewey & Co., S. F.COFF'S HANDBOOK OF MINING LAWS.—Containing the
U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877.
Pocket size, and very handy and convenient for miners.
Post-paid, \$1.00. Sold by Dewey & Co., S. F.

Office, No. 320 Sansome street, Room 10.

Mining Books.

Orders for Mining and Scientific Books in general will
be supplied through this office at published rates.

With Adjustable Out-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

More New "Processes."

The periodical excitement in the metallurgical "process" line is again under way. This time the particular localities attacked are Grass Valley and Meadow Lake, both well-known and prominent "bone yards" of processes, where many a one has come to an untimely end when brought to the test of experience on a large scale.

It is stated that a process is being worked by the well-known Murchie mining company, of Grass Valley, by which they have succeeded in reducing the base and rebellious sulphureted ore of one of their mines, by a simple method of amalgamation. The expense of the new way of treating the sulphurets is said to be \$6 to \$8 per ton, where the chlorination process, the best previously used, cost from \$16 to \$18 and higher. The Murchie is a large company, owning the Big Blue, Independent, Lady Alice, Red, White and Blue, etc., and having an 18-stamp mill, with 10 Frue concentrators, etc. The fact of a company of this character taking hold of the new process has given it a sudden prominence which it would not otherwise have had so soon. It is stated that they get 88% of both gold and silver. The inventor is James H. Smith, sometimes known among mining men as "Secor Smith," from a former connection with the Secor process. The new Smith process is kept a secret at present, and we know no more of it than that the Murchie company are supposed to be sending down bars resulting from a mode of working sulphureted ore by amalgamation instead of chlorination. It is not claimed to be the subject of any patent, so far as we can learn.

The principal excitement in this line, however, is at Meadow Lake, the rebellious ore of which district have resisted every attempt yet tried to work them. The district is a famous one; the ledges numerous and ores rich, but rebellious. A large town was built up there, mills erected, but the whole thing had finally to be abandoned through failure to treat the ores. Every now and again, however, when a new process comes to the front, it is expected that Meadow Lake will be started up again.

This time the local papers consider that the enigma is solved, and that there will be dividends, at least, from Meadow Lake ores. Numbers of people have gone to the district, and some expensive purchases of mines are said to have been made.

The process which has brought this about is one devised by Mr. James Gould, who was formerly at the Black Bear mine, in Shasta county. It is claimed that his method treats the ores which have defied all other processes. The Gould process, as described in the *Truckee Republican*, which is quite jubilant over it, consists simply in partially roasting the ore before crushing, then crushing it in a stamp mill; heating the pulverized mass to a cherry red in an ordinary furnace, and then amalgamating it by a simple pan process. In this way, it is stated, 13 tons of ore yielded \$1,281.80, or nearly \$100 per ton. Assays of tailings showed that \$5.56 per ton of the gold escaped. If these figures be correct, it shows a saving of 95%.

We can see nothing especially new in the process as described above, the same treatment of ore having been tried before. Whether roasting the ore previous to crushing will make any difference we are not informed, but this has been done in several of the processes which have recently come to the front, but which have only appeared to disappear. We refer to those where ore was roasted and dropped into solution supposed to put them into condition for amalgamation. This system was tried very many years ago, so that if practically successful on a large scale it would be recognized now.

However, we have not heard that Gould wants anybody to buy rights for his process, or in fact, that he has or claims to have any patent, and he is entitled to a respectful hearing. If the gentleman has succeeded in doing what the local papers say that he has—and they ought to know, being close at hand—he will be

doing a great benefit to the mining community, since a success at Meadow Lake will make a success at other places.

We should like, however, to see more explanations of the rationale of the process, and see wherein it differs from others which have gone before. No doubt the work already accomplished will stimulate the owners of the mines at Meadow Lake to test the matter thoroughly in a way which will be satisfactory to those directly interested, and to the public at large.

The Monte Mayor Mines.

In our issue of July 26th, we gave a description and map of the mineral district of San Salvador. Herewith we present a geological section showing the position of the veins in the Monte Mayor mine, in the district referred to, which is in the department of Colera, Central America. There are six mines belonging to the Monte Mayor mining company, of which the Monte Mayor is the most important. The mines were owned for some time by Manning & Co., of Liverpool, who had advanced money on them, but they are now owned by the company referred to.

The shaft shown in the engraving is full of

Why do Springs and Wells Overflow?

A new theory in answer to the above question is broached by Nelson W. Green in the *Popular Science Monthly* for November. Mr. Green says the overflow is caused by "the resultant of the earth's centripetal and centrifugal forces acting impulsively upon the subterranean water deposits, and tending to force them into and through the natural channels of the earth's crust." It is claimed that while the overflowing of wells and springs has been accounted for by scientists upon the supposed existence of hydrostatic pressure, a more careful investigation justifies the conclusion that such a proposition is fallacious, although exceptional cases may occur. Aristotle and Seneca suggested the central heat of the earth as the force which operated to compel the water to seek an overflow, but this is not borne out by experiment, neither is capillary attraction a satisfactory explanation. The controversy, if any there be, is confined to those subterranean waters of the earth which are not influenced by rains.

Among the many examples cited against the hydrostatic theory, and in support of the centrifugal and centripetal forces, Chautauqua lake

water imprisoned in the rocks, that the resultant of the two natural forces, centripetal and centrifugal, are duplicated upon every point of the inside surface of the rock prisms, and tends to force the water out when the cavity is perforated. The direction of this force is placed at 45° from the direction of the force of gravity, but it remains unimpaired should the opening lead in a contrary direction. Hence, if fissures exist in rocks that lead to imprisoned waters, it would happen that through these outlets the waters must certainly flow, and, if by any artificial means, as by boring, an opening should be made between a body of confined water and the surface of the earth, a flowing well would result. "Of course," says the writer, "it must not be understood that this would happen if the body of water supposed were an isolated one and completely unconnected with other bodies of water through channels and intercommunications known to exist in the various ramifications of the earth's surface." Why should it not if the theory be correct? If the two natural forces referred to are continuous upon a string of subterranean reservoirs, why should they cease to operate upon an isolated one? If it be necessary in support of the centripetal and centrifugal theory to create a vast series of subterranean reservoirs connected with each other, there can be no necessity for the theory, since hydrostatic pressure can explain the phenomena of water flowing from the tops of the highest mountains under a similar arrangement. Nay, a common force pump in the hands of a man can overcome the Garrier theory, and why not the immense forces of nature?

It is true that the centrifugal force tends to throw particles from the earth, but the centripetal force tends to the opposite, and both being equal, the effect is the same as if neither existed. Otherwise, it would seem as if the resultant of the two forces, being more powerful than either one alone, would affect other things in or upon the earth. There may, however, be reasonable grounds for suspending the operation of gravity or centripetal force, to a certain degree, to explain the overflow of springs and wells, which cannot easily be explained by hydrostatic pressure, for it is certainly true that strong and abundant overflows occur at the tops of mountains and on high plateaus; and admitting that hydrostatic pressure causes the overflow of springs and wells in particular localities, it would still be necessary to explain how water gets to these highest points. Mr. Green says this can best be done by his theory, in which the force is always acting upon partially confined water-beds and water-channels forming the internal water-structure of the earth's crust. The conditions necessary to the realization of the best results are that these water-deposits shall be more or less imprisoned and the outlets comparatively limited. The overflow will be continued and upward until the resultant is overcome by friction. We are hardly prepared to accept this theory without further investigation, for one reason of many, because friction does not overcome the resultant in very deep flowing wells, while in shallower wells the water, although abundant, does not rise to the surface, whereas the contrary would seem to be the case, the resultant having less friction to contend against.

CALIFORNIA GRANITE QUARRIES.—At Penryn, Placer county, the granite quarries of Mr. G. Griffith are working a force of from 50 to 200 men. The granite is quarried at a depth of about 100 feet below the surface, and is taken out in blocks of from 10 to 40 tons. This granite is considered of very superior quality, containing less iron than the Eastern varieties, and as to polish, it is *par excellence*, as the many buildings in this city will testify, particularly the polished columns of the Stock Exchange. Mr. Griffith has also a quarry of Black or Egyptian granite, from which the handsome buttresses for Mr. Flood's residence at Menlo Park were made. A bid has been put in by the proprietor for building the Oakland Masonic Temple of granite from this quarry.

It is stated that Gen. Sherman has written to a military friend in Chicago, that Gen. Grant has an important message to deliver to the people of the United States, which he will give to them first when he reaches that city.

THE MONTE MAJOR MINE, SAN SALVADOR.

water, and has been for some time, but a steam pump will be sent from here on the 20th, by which it will be pumped out. The Monte Mayor consists of three veins parallel or rather converging towards each other, respectively five, seven and two feet wide.

It is stated that at A is an excavation in which very rich ore was found, native silver hanging on the walls and in the fissures of the cavity. The vein matter on an average paid about 64 ounces per ton in gold and silver, in the proportion of four to six, or about \$129 per ton. The shipping ore was up to \$1,000.

The water-wheel is an iron one, brought from England, and by means of the creek, furnishes water power for the arrastras during five or six months of the year.

The permanency of the San Salvador mines generally, is proven by the Loma Larga mines, the Tabanco, Equeutos and Corozal, all of which have been producing metal continuously for over 15 years. The district is very little explored. The climate though tropical is nevertheless quite healthy. Mr. Guido Kustel has examined and reported on these mines, and the company who has secured the mines and now about to work them are nearly all San Francisco people. The ore has previously been worked by arrastras, but a mill will shortly be sent down. Some of the ore was brought to this city and worked with very satisfactory results.

The furnaces in blast in Scotland now number 90, as compared with 96 at the same time last year. These produce about 195 tons weekly per furnace.

is mentioned as being situated on the highest land in the State of New York west of the Catskill mountains, without any adequate feeder. Yet a large mill stream issues from it; in fact, the lake is 20 miles long by two miles wide, the whole body of which is fed by springs bubbling up from the bottom of the lake. The whole mountain region of northern Pennsylvania is referred to as another good illustration of high springs, which are claimed to be beyond the reach of hydrostatic pressure. The White and Adirondack mountains are also full of similar cases.

It is generally held, according to M. Garnier, that "unless there be a reservoir higher than the surface whence we intend to bore, we cannot hope to obtain an overflowing fountain." Instances may be multiplied to show the fallacy of this assumption. The Himalayas, the highest mountains in the world, pour continually out of their highest points great cataracts and streams, with an abundance that would exhaust any possible reservoirs at their extreme tops. Now since this is the highest land of the world, no higher source is possible, and hence the conclusion is inevitable that these great overflows are due to some other force than hydrostatic pressure. That gases may force water up may be shown to be erroneous, for the reason that gases do force water down when both are enclosed by a common receiver. This, says Mr. Green, may be seen any day at the gas-works. But he omits to explain the action of carbonic acid gas, etc., in soda fountains, fire extinguishers, etc., which invariably throw the water in any direction in which the nozzle may be pointed. Mr. G. supposes in this case of

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

El Dorado County Mines.

EDITORS PRESS:—I see in my last letter, in writing about the Sardine mine, on Main Bar, American river, owing doubtless to my careless caligraphy, the Superintendent's name is printed Session, it should have been Mr. Thomas Simons, a gentleman well known in the mining world, both in Colorado and Nevada.

Golden Ophir.

Since my last I have visited this mine, but unfortunately on the day of my visit the mill was not at work. Mr. Folger, the Superintendent, informed me that the new machinery moved highly satisfactory, and the ore from assay tests was most promising. I am told that recent assays gave a return of between \$400 and \$500 a ton in silver. Mr. Hobart, who made tests of the ore by the new Robertson process last summer, found the sulphurets to be very rich, and made the company an offer to put his sulphuret-saving machinery below the Huntington rifles, as they now exist, but his offer was not accepted. Until I have an opportunity of seeing this mill in operation I shall refrain from writing about it, beyond saying that, admitting it to be all that is claimed for it, I doubt its capacity to work a sufficient quantity of ore in a given time, to be remunerative, especially as the slate neither works nor discharges from the screens as freely as quartz does, and being so much thicker in the pulp requires an extra amount of water, thereby retarding the settlement of the sulphurets. I am satisfied that with really efficient machinery, adapted to the peculiar nature of the ore, the "Golden Ophir" will prove a valuable property, and fully justify Colonel Bilty's persistent efforts to develop it.

The Argonaut.

This mine, situate some one and a half miles south and three-quarters of a mile east of the village of Greenwood, a lively and prosperous mining camp, even yet, owing to the many mining locations which centralize here, is now being thoroughly explored and prospected by a San Francisco company, Hon. Paul Neumann & Co., who some time since bonded it from the locators, Messrs. John and Thomas Smith, Maltby and Garcia, who had partly opened the mine, and erected a ten-stamp mill thereon. The present company have worked no ore in the mill, but have been several months at work in thoroughly opening the mine. On the surface the lode measures 64 feet in width, which led to the opinion of some experts, that it was a mere mass of float ore. The new company have run a tunnel, now in over 400 feet, to tap the supposed ledge, at a depth of 200 feet below the surface, and in doing so, have passed through a quartz ledge, 39 feet thick, showing handsome prospects of free gold, visible to the naked eye, with well-defined walls; a second ledge, upwards of 8 feet in width, which also prospected well, and they are cutting through a third ledge, which is now penetrated for 43 feet, and bow much more there is to be cut through remains for time and powder to develop. That this is a mother ledge is certain, and if the whole body of ore will pay for reducing, even if of a low grade, this will make a permanent and profitable mine. It is evidently in the right hands, and Mr. McNevis, the well-known mining engineer, has spent all this summer directing the prospecting in it, as well as attending to other mining property in this county. The success of this mine is important to this section, both as to the impetus it will give to business generally in this neighborhood, and stimulating capital to seek other investments in the numerous locations that await its aid both here and in other parts of El Dorado county.

The Golden State Mine.

Owned by a private company, consisting of Messrs. Armstrong, Hall, Jones, and another gentleman whose name I forget, is situate on Jones' creek, some seven miles from Greenwood, on the north side of Canyon creek, near the village of Jones' Hill. This mine is more of a series of seams than a lode; has been steadily worked for many years, and has always been a profitable mine; nor is there any indication of its ceasing to be so for many more years to come.

The Clipper Mine.

Mr. E. W. Hulford is now engaged in opening the Clipper quartz mine, some 3½ miles above Georgetown, for a San Francisco company. Rich ore has formerly been taken from this mine, when in the hands of private parties, and under the management of Mr. Hulford there is every assurance of its being added to the list of successful investments in mining property in this county. Renewed activity in the various quartz mines around Georgetown is one of the indications of increasing confidence in our mineral wealth, which in the near future will not be confined to gold alone, as old "El Dorado" can boast of good copper deposits, slate and asbestos. Cinnabar also exists, but whether sufficiently rich to be profitable remains to be proved. That slate of fine quality exists is a known fact, but it can only be utilized when increased population and improved facilities for transportation shall have enlarged the demand

and reduced the expense of removing from quarry to market.

Mineral Lands.

I see that Mr. Dana Perkins, a land agent for the C. P. R. R., urges the necessity of compelling miners to prove up on their locations, and of forcing all land not actually in use for mining into the market, especially all such land as has been allotted to the railroad corporation. Such a consummation would most certainly be very detrimental to the future prosperity of this county, teeming as it is with mineral, which, if locked up in private hands, would practically stop the nomadic race of prospectors, the pioneers of all mining developments—men who spend their lives looking for a strike, almost invariably poor, and yet ever the discoverers of lodes and deposits for the ultimate benefit of others and enrichment of the State. As an old prospector told me a few years ago, when I met him, after twenty years of toil in the mining camp he was then leaving, with his blankets on his back: "Yes, I'm off for El Dorado, Amador and Kern counties. There are too many clothes lines and fences here now for me, and a fellow can't prospect any more without trespassing on some fellow's poison oak ranch. I've done well here at times and opened several good mines, but I'm broke now."

Greenwood, Oct. 27th, 1879.

Fire-Proof Rock in California.

EDITORS PRESS:—Many years ago a stratum of peculiar clay was discovered near Milwaukee. It is from which a kiln of bricks were made as an experiment. They proved of a yellowish color and were unsalable. In the lapse of time it was noticed that wherever those yellow, worthless bricks had been used in connection with limestone in the construction of furnaces, the bricks were as uninjured by fire as were the limestones—till then the principal reliance for furnaces, forges, chimney-backs and the like.

At once the old dis-used clay-bank was revisited, large kilns of brick put up, and the city of Milwaukee had a near and ready source of great wealth.

Soon the Milwaukee fire-proof brick were in demand all over the States, and Canada; nay, more, were shipped across the Atlantic and around the Horn. Most of the steamer furnaces, hotel furnaces, mining and smelting works of the Pacific coast have been built with Milwaukee bricks imported at a cost of about 10 cents apiece!

Now, right here in Sierra county Cal., a ledge of rock exists that is singularly unaffected by the intense heat and the most sudden plunges into cold water thereafter, though repeated any number of times. The ledge is stratified just right for quarrying, water power is abundant and right at hand, in fact, crosses the ledge. No dam, even, is necessary, only a short flume. The rock is soft, yet tenacious, admirably adapted to sawing into blocks as desired.

A stage road passes within a few rods of the ledge, and the C. P. R. R., is but a half-day's drive away.

This fire-proof rock can be fashioned to suit, and laid down on the wharves of San Francisco, on the depots of the mining towns of California for one-quarter the cost of imported bricks, while in many respects it is 10 times better, as large blocks or peculiar shaped ones can be made at pleasure, thus saving expense of mortar while securing greater strength and durability.

What enterprising man or firm will take hold of and develop the new source of wealth? Consider what Milwaukee bricks have cost this coast, and, if this fire-proof rock is equally as good, it is easy to see that "there is millions in it."

J. G. LEMMON.

Sierra Valley, Oct. 22d, 1879.

Globe District, Arizona.

EDITORS PRESS:—In my last communication I made an assertion that I thought that there was here a fine opening for investments, and in order to show the public how it is, will give an outline of one which I have visited and examined, and tell what I saw. This property lies only one-quarter of a mile from abundance of water (Pinal gulch), and on its surface shows croppings of large width and at the shaft we find pay ore at least four feet wide. The shaft was sunk 40 feet through the hanging wall, and at that point cut the vein, showing pay ore three feet thick. The shaft was then put down 60 feet, following the footwall, making a total depth of 100 feet. In the bottom there was found 18 inches of extremely rich horn silver ore, which glistened and sparkled in the candle light like diamonds. Now, back to the surface and on the dump, we find no trouble to get ore assaying up into the thousands. We go out to the croppings and follow them northeast for 90 feet to end of claim and find they carry ore, and in places even eight feet wide and crossing the line three feet on adjoining claim, find a shaft 25 feet deep, showing good ore. At the bottom find workmen drifting southwest to dividing line, and here we find three feet of rich ore.

Having now examined enough to form an idea, will see what the terms of the owners are,

which are these: They ask for a body of ore 3 feet wide, 25 by 40 feet deep on ends and 90 feet long, all of which is in sight, and place the price at the value of the small sum of \$50 per ton, leaving out all ore in the 60-foot shaft, also supposed body unexplored southwest of shaft, which has as good experience as the northeast side. Then another item, lying on the north of the ledge are several strata or spurs. Two have been prospected and carry ore from six to eight inches wide, out of which can be got assays of immense value.

Now, having facts and figures before us, I would ask where and by whom is there any such inducements held out to investors, and this is only one of a great many properties that are offered at such prices. I think the amount of ore, as well as price, at a large per cent. below actual value. So looking at all sides I fail to see how an investor can fail to realize a handsome profit, for as depth is reached these spurs must connect with and make the ledge that much larger, as well as richer. Now, as the question may arise in the reader's mind, if these parties have all this ore, why do they wish to sell, and I will answer. The only means of reduction here at the present time is a five-stamp mill (the Isabella), and their terms are \$25 and \$45 per ton, guaranteeing but 80% of assay, so you see the inducement held out to those having low-grade ore.

In my other I tried to show that, with machinery here, ore ought to be worked as cheap, if not cheaper than in most camps, under as good management; and these two claims are not the only ones on this ledge, for it is traceable for about six miles in length, and having all indications of permanency.

Having now given you an idea of some of our low-grade ore, will cite you to the returns of the Isabella mill, commencing August 26th and ending September 30th. During that time there was worked 180½ tons, giving a gross yield of \$50,047.50, or an average of \$277 per ton of 2,000 pounds. This was taken from 19 different mines, showing we have a goodly amount of high-grade ore.

MINER.

The Lick Observatory.

The *Science News*, speaking of the above observatory, points out the value of the California climate for favorable astronomical observations. It says: During the last four years, very little has been heard of the observatory to be built in California from the gift of Mr. James Lick, and the public has very generally supposed nothing would come of the project. But there are now signs of a renewed activity on the part of the trustees, and evidence of an intention to carry the project through without further delay.

In August last, Mr. S. W. Burnham, of Chicago, the well-known observer of double stars, was invited to spend a month or two on Mount Hamilton, with his telescope, in order to test the suitability of the mountain as a site for the proposed observatory. His reports were so favorable that Prof. Newcomb, on whose recommendation he was chosen for the work, visited the place himself in September. Both these gentlemen speak in the highest terms of the excellence of the astronomical conditions. Not only is almost every night perfectly clear, but, according to Mr. Burnham, bad seeing is almost unknown. Every night is such a one as he would consider superb at Chicago, and would only meet with two or three times a year. He discovered during his stay a number of new double stars, in portions of the sky which are further south than can be thoroughly examined in the comparatively bad atmosphere of stations this side of the Mississippi.

The result of this exploration will give both the trustees and the public a new interest in the project, and it is supposed will lead the former to push the work on as rapidly as possible. If, as both the astronomers who have examined the site seem to suppose, its atmosphere is finer than that of any existing observatory, the result will be that the most powerful telescope in the world will be under the finest sky for supplying its utmost capacity.

PUSHING AN IRON BRIDGE ACROSS A RIVER.

A notable feat in engineering was brought to successful issue in the latter part of September, at Dinard, in the department of Ille and Vilaine, France. In carrying a railway across the river Rance, the novel plan was adopted of building the bridge on shore and boldly pushing it bodily across the stream. The bridge weighed 2,600,000 pounds; its height above the river was 100 feet, and the length of the main span 314 feet. Twelve windlasses were used in rolling the bridge into position. It was calculated that four or five days would suffice for the work of putting the bridge in place, but owing to the breakage of chains, it took two weeks.

KRUPP OF ESSEN.—The cast steel manufactory at Essen has existed since 1810. It has been conducted by the present owner, Herr Alfred Krupp, since 1826, and since 1848 for his sole account. The number of workmen, at the close of 1878, was 8,500. There are in these works 1,648 furnaces, 77 steam hammers—the largest of all weighing 50 tons—18 trains of rolls, and 1,062 machine tools.

Tombstone District, Arizona.

The *Weekly Nugget*, published at Tombstone, Pima county, Arizona, in its last issue gives the following account of the surroundings of the above district.

To the south of us, a distance of 15 miles, by prospectors' trail, lies the Mule mountains, having derived their name from the pass in that range which is only traversable by loose or pack animals—mule pass—and over which rail most of our smuggled goods are brought in. These mountains, or the mining section therein, cover a space of about 15 miles square, perhaps not as far in an east and west direction, but about that north and south. The country is located for mining purposes from the north end of the pass through the entire range, for a distance of 15 miles. On the north the mines show both gold and silver, the gold predominating, and in the center copper is found in enormous quantities, so much so that flux in sufficient amounts is hard to obtain. At the south side, and about 15 miles from the Mexican line, lie the silver claims from which such good reports have recently been received, and which contain a vast amount of that metal and will, sooner or later, produce a stir among our mining people. As is too general, this district is classed as "low grade," which is not the case; the ore generally assaying into the hundreds, and which by proper treatment would yield large profits to those who invest in reduction works. The San Pedro river lies from seven to eight miles from these mines, and furnishes abundance of water for all milling purposes, and, in fact, is less distance than is usual for mining companies to transport their ore. Water is scarce in this camp, except about Dyer's camp, where persons traveling that way, find a hospitality which is more than unusual in frontier countries.

From Mule mountains to the northeast, but little prospecting has been done, on account of the scarcity of water. From persons who have been through there, we learn that many large leads, of unknown value, have been seen. These claims have not been located from the fact that these parties were "thirsty," and seeking a more congenial spot for themselves and animals. The route is almost level to the Swiss-belt mountains, in which the St. Louis company are now putting up their mill for the reduction of the ores from the valuable mine—Swiss-shelm—which gave name to that group of bills. From Swiss-shelm's Camp, Rucker is the supply point for provender and is very convenient, while the necessary lumber for building purposes can be had at Morse & Co's mill, in the Pinery canyon, close at hand, and which mill is now engaged on a contract of two or three hundred thousand feet for the before-mentioned St. Louis company. This mill is distant some 15 or 18 miles from Camp Rowie, and the once dreaded Apache pass, and about 20 miles south or southeast from Dos Cabezas gold mines, which point is attainable by the stages of the National Mail and Transportation Company, running between Tucson and Mesilla, N. M.

Dos Cabezas district, as defined by the records, is a gold district, and covered by from 100 to 200 claims, and from which a great deal of bullion has been produced, and could be now, if the necessary appliances were at hand. E. Martin Smith, of whom everybody knows, and P. W. Smith, of the Pima County Bank, are largely interested here, and, in consequence, these valuable "diggings" cannot lie idle long. From Dos Cabezas to the northwest lies what is known as the silver district, and where many claims have been located, producing enormous assays in silver, but upon which little work has, so far, been done, except the title assessment work. Further on from this point, and, in fact, all the way to Camp Grant, is a country filled with mineral, but is, as yet, almost unknown to the prospector, and which so far as has been traveled, is known to abound in silver ore.

However, there are miles of promising country closer about us. Commencing at a point about Tres Alamos and following down the San Pedro for a distance of, say 25 miles, and branching off to the east as far as the stage road, is a country which undoubtedly contains gold and silver, and which has never been looked at by our experienced prospectors. Considerable ore is brought from there by passers-by resembles that of the Tongh Nut of this camp, for silver, and some "born-spooned" specimens have shown a fine prospect in gold. Farther down the San Pedro are the mines which have already created their commotion, and which are known to be more than good. These all lie on the east side of the river. On the opposite side—the Santa Catarinas—is supposed to be a group of mineral, in fact, many mines have already been located and give promising assays. This range has hardly been touched by prospectors, from the fact that none who are able have ever discovered and worked a "bonanza."

A STRONG BANK.—The Bank of England was incorporated in 1694. It covers five acres of ground and employs 900 clerks. There are no windows on the street; light is admitted through open courts. No mob could take the bank, therefore, without cannon to batter the immense walls. The clock in the center of the bank has fifty dials attached to it. Large cisterns are sunk in the courts, and engines in perfect order are always in readiness in case of fire.

MECHANICAL PROGRESS.

Moving the Egyptian Obelisk.

Lieut. Commander Gorrings, U. S. N., and his assistant, Lieut. Schroeder, have sailed for Liverpool, on their way to Egypt, to superintend the removal and shipment of the Cleopatra Needle presented by the late Khedive to the city of New York. The machinery to be used in handling the monolith has been prepared at the Roehling Works, Trenton, under the direction of Mr. Gorrings. The *World* says that this machinery will aggregate about 80 tons in weight. It consists of two towers, each 26 feet in height (which are to be shipped in sections and put together after their arrival in Alexandria), two steel castings, each weighing over six tons, and a cradle 60 feet in length. The towers correspond to the sides of a gun carriage, and the casting to the trunnions on a gun. Like the machinery for handling the monster gun of the colossal Italian ironclad *Duilio*, this machinery for moving the Alexandrian obelisk will command the critical attention of machinists and engineers; and it is satisfactory to know that the work of transferring to the New World this great Egyptian monument will be carried out entirely under American auspices.

The method of embarking the obelisk is described as follows: A steam collier having a water ballast compartment will be secured alongside of the pier, and the necessary preparations made for heaving her down to careening lighters placed alongside on the side opposite to the pier. The water ballast compartment will be filled. A port having been opened to admit the obelisk into the fore-hold, it will be launched in. The listing of the steamer from taking its weight will be overcome by heaving down on the careening lighters, and the sinking due to both operations will be counteracted by pumping out the water ballast compartment, thus removing a weight of water corresponding to that of the obelisk. Tidal and wind-drift differences of level will be overcome by means of a float secured at the shore end after the fashion of a ferry-slip.

COMPRESSED AIR FILTER.—A new filter has been devised by M. Chanoit, which works on the ascensional principle, and in which the filtered water is made to compress air and so become itself aerated. The purifying medium used is a preparation of iron slag from blast furnaces. The pressure of the main or other source of supply forces the water upwards through the filtering material, the supply pipe to the filter being reduced so that the pressure is brought on slowly and gradually, in order that the filtration may not be too rapid. The air contained in a reserve or storage chamber is compressed by the pressure of the water rising in it, and this compressed air serves to aerate the filtered water, and subsequently assists in giving force for its distribution to the upper stories of a building or wherever it may be required. The filter casing is made of galvanized iron, neatly painted outside, and fitted with nickel-plated draw-off, distributing and cleansing taps. The filters are made in various sizes, to filter any quantity from one quart per minute upwards. The filter is self-supporting, and can be easily connected direct to the main service pipe, or to a cistern or tank fixed at a greater elevation than the apparatus itself, so as to get the necessary force to feed it. The manufacturers adopt a modification of the arrangement for fixing in cisterns or large tanks for railway stations and other large establishments. The following are the advantages claimed for this filter, viz: That it is self-supplying and almost self-cleaning, the operation being performed very rapidly; and that by means of this apparatus, pure and aerated water can be supplied to every floor of the largest houses, in town or country. The filtering material does not require to be renewed so frequently as in other filters, but will, it is said, remain in working order for years, and will not foul the water, however long it may remain in contact with it.

CONNECTING-LINKS FOR CHAINS, ETC.—The following method of constructing chain-links is suggested by Herren S. & M. Rosenberg, of Cassel: A link, similar in form to that of an ordinary chain-link, is split or divided into two separate parts at a slight angle to its two flat faces, so that each part is somewhat thicker on one side than on the other. On the thicker side of each half is an undercut projection of a thickness and form corresponding to that of the transverse section of the complete link, and on the other side there is a gap or opening corresponding exactly with such projection, so that when the two halves are slid on to each other, the projection on the one half fits into the gap of the other half, and thus the two halves are secured firmly together, the ends of the gap of the one part being dove-tailed so as to fit into the corresponding dove-tailed ends of the projection on the other part. For securing together the two ends or parts of a chain, or the two eyes or loops of a rod or bar by means of this link, the two halves are first separated, and the links to be connected having been inserted through the gaps thereof, the halves are slid together as described, whereupon they will securely hold the chain until again slid apart by hand.

A Remarkable Railroad.

The Mount Washington railroad is a marvel of engineering. It is three miles in length, and rises 8,625 feet, or one foot in four. The principal feature of the railroad is the cog-rail in the center of the track. On each driving-shaft of the engine is a cog-wheel. The teeth catch the cogs in the center rail, propelling the car up the mountain. The boilers of the engine are inclined downward, and when on a steep grade are quite horizontal. Every locomotive takes one car, and is provided with a double set of driving-wheels, that any danger from broackage of machinery is prevented. The ascent requires one hour and a half, and one could step off and on at any point. The track is strongly built, and is daily inspected by the men continually employed to police it. In ascending, persons in the forward car have their feet on a level with the heads of those who sit aft near the engine, which, going up, is the propelling power, and going down, the repelling force.

The steepest point is Jacob's ladder, a trestle 30 feet high and 300 feet long, the grade 1,604 feet to the mile, or thirteen and one-half inches to the yard.

IMPROVEMENT IN SHIPS.—A nautical invention has recently been brought out in France. The invention consists in forming the upper portion of the bulwarks of ships, of loose sections, composed chiefly of hollow, thin metallic tubes, divided into compartments by diaphragms, the sections to be about 12 feet long; these are to be divided into a number of compartments of suitable form, and provided with projections on their under sides, so as to be fitted on to the place of the top rail of the bulwarks, serving as a substitute therefor. These sections, when immersed in the water, would form so many pontoons, and, being provided with cords and loops along their sides, would, in the event of the ship going down, be lifted out of their place by the action of the water. It is likewise proposed to construct the seats on the deck in the same manner, and underneath every seat, and along the entire length of the bulwarks, other floating tubes may be provided. In the case of sea-going vessels, the bulwark tubes are fitted with holes, rings or slots, so that in case of foundering they can at once be joined together either before or after taking to the water.

IMPROVED METHOD OF LUBRICATION.—In a recent French invention the screw is applied to lubrication of shafts and other parts of machinery. In the case of a shaft, the oil is poured into a reservoir below, and a screw placed slantingly in the tube raises oil to the level of the shaft, whence it is distributed by channels over the breadth of the journal. The axis of the screw rests on the bottom of the reservoir, and its head turns in a bearing fixed in the tube. Motion is communicated to it from the shaft by means of gearing with helicoidal teeth. The impurities at the bottom of the reservoir are neither stirred nor carried up. The velocity of the screw is adapted to the lubrication required. If the shaft has a high velocity that of the screw is diminished, since the shaft is subject to slight pressure; but if the shaft turn slowly, the velocity of the screw is increased, so as to raise more oil because of the strong pressure. Thus a regular, continuous and economical pressure is obtained.

PORTABLE AND TRACTION ENGINES.—The following method of constructing the carriages and brackets for carrying the crank-shafts of engines of this class is adopted by Messrs. Clayton & Shuttleworth, of Lincoln. The bracket is firmly bolted on to the hoiler, and on this bracket is mounted the carriage, which is secured from lateral movement by a tenon fitted in a mortise or groove in the bracket, and from vertical movement by flat-sided bolts, which pass through the tenon and the sides of the groove in the bracket. These bolts tightly fit the respective bolt-holes, except at the part where the bolts pass through the tenon, at which place the bolt-holes are made longer than the width or diameter of the bolts, thus allowing the carriage to slide longitudinally on the bracket as the boiler expands or contracts, whilst at the same time the distance from the cylinder to the center of the shaft is preserved by a stay, in the usual manner.

NEW DAMPING APPARATUS.—Mr. William Mather, of Salford, county of Lancaster, England, has patented an improvement in apparatus for damping woven fabrics by means of a spray or sprinkling of water upon the fabric after starching or stiffening. It consists of a damping roller made of metal, with an engraved surface. The damping roller revolves in a trough containing the water, and a doctor, of India rubber or other suitable material, is applied to the damping roller to remove the excess of moisture. The fabric or other material is pressed against the damping roller by a roller supported in a swing frame.

NEW MINING SLUICE.—Mr. Samuel M. Eddy, of Dalton, Ga., has patented a simple, easily operated, and efficient apparatus for washing gold from the dirt, stones, etc., with which it is mingled. It consists of a rectangular trough provided with gates, bars, or bridges, intervening pockets, and zigzag ribs or bars, for obstructing the material and supplying places for receiving and retaining the precious metal as it gravitates from the gold-bearing dirt or sand.

SCIENTIFIC PROGRESS.

Corrosion of Boilers by Fatty Matters.

The Chief of the Experimental Railway Company of France, M. A. Mercier, gives, in the *Annales des Mines*, the results of some experiments upon the changes produced by fatty matter in the wrought and cast-iron parts of engines exposed to the action of steam. M. Mercier had occasion to examine in the laboratory some hard balls taken from the cylinders of steam engines, and which were generally attributed to the use of acid lubricating oil. The balls, when crushed and digested in ether, left an insoluble residue of peroxide of iron, while the soluble part was composed of oleic acid, combined with the oxide of iron mixed with a non-decomposed oil.

A series of experiments was made to determine whether the formation of this oleate of iron resulted from the use of oil more or less rancid, having an acid reaction, or whether it was the product of the decomposition of neutral fatty matter in presence of iron and of steam at a high pressure. According to these experiments, the fatty matters have no need of being acid or rancid, nor of being heated above 212° F., to decompose steam in presence of iron, and thus produce oleate of iron, glycerine and hydrogen. Observations made upon steam engines which showed corrosion in those parts exposed to oil and steam, suggested the following experiment: An iron bucket containing wrought-iron chippings, thoroughly saturated with oil of colza previously neutralized, was left during eight days in a reservoir supplying steam to several steam hammers. At the expiration of this time there were taken from the bucket about 30 cubic inches of very thick oil, which flowed with difficulty and emitted an odor similar to what is produced by the action of an acid on iron; the iron was strongly corroded, and the oil-colored to a dark brown and entirely soluble in ether—contained 7% of the oxide of iron. This oleate of iron oxidized rapidly on contact with air, and, like all the minimum salts of iron, gave up some peroxide of iron; when again placed in contact with iron it attacked the iron and was thus brought back to its first state of saturation. In this manner can be explained the large proportion of non-combined peroxide of iron contained in the matter found on the valve-face of an engine at Valence, upon which an observation was made.

These facts appear to clearly explain the corrosions of certain boilers receiving fatty matters brought over from the cylinders by the exhaust steam, or used to lubricate the throttle valve of locomotives.

In locomotives the steam is generally taken from the upper part of the boiler by means of an immersed slide throttle valve; the oil used for lubricating the latter becomes saturated with iron, and being thus made heavier than water sinks to the bottom of the boiler where it attacks the iron plates, forming in them those excavations which are only found when feed-water is used of such purity as not to deposit the lime-scale that in most cases preserves the boilers.

The use of mineral oil, thickened if necessary with wax or paraffine, for the lubrication of moving parts placed in the steam, would he without doubt a good means of preventing changes in the material of such organs.

THE RAIN TREE.—Some travelers in Columbia, South America, in traversing an arid and desolate tract of country, were struck with a strange contrast. On one side there was a barren desert; on the other a rich and luxuriant vegetation. The French Consul at Loreto, Mexico, says that this remarkable contrast is due to the presence of the "Tamai caspi," or the rain tree. This tree grows to the height of 60 feet, with a diameter of three feet at its base, possesses the power of strongly attracting, absorbing and condensing the humidity of the atmosphere. Water is always to be seen dripping from its trunk in such quantity as to convert the surrounding soil into a veritable marsh. It is in summer especially, when the rivers are nearly dried up, that the tree is most active. If this admirable quality of the rain tree was utilized in the arid regions near the equator, the people there, living in misery on account of the unproductive soil, would derive great advantages from its introduction, as well as the people of more favored countries where the climate is dry and drouths are frequent.

ORIGIN OF LANGUAGE.—A Frenchman named Clairfond has published a small work in which he revives the argument that the earliest attempts at human speech were imitations of natural sounds or the cries of animals; and he contends that out of recollections and repetitions of these sounds the names of certain natural phenomena, and of animals and other objects, originated. He finds numerous examples in the French language, and thinks that proofs might be found in other languages if search were made, and suggests that the Geographical Society of Paris might furnish instructions to their travelers to collect from among the natives of different countries all the sounds traceable to the source indicated above. M. Clairfond is of opinion that the series of sounds, words and expressions thus collected would aid in the discovery of the origin of language. Taken in connection with natural sounds, the origin of words in our own language—such as thunder, sigh, whisper—becomes evident.

Bog Ores.

The roots of trees appear to have power to reduce the peroxide of iron, contained in sands with which they come in contact, to the soluble protoxide. When the water which dissolves this runs into low places, where branches, twigs and leaves of trees are slowly decaying, the protoxide becomes reoxidized and is deposited in the interstices of the vegetable forms left by the decomposition of the woody fiber. Thus, parts of the trees are not petrified, but ferrified; and whole beds of iron ore consist of these roots of dead vegetation. Where the ferruginous waters do not encounter masses of decomposing wood, but merely lie at rest, as in swamps and ponds, the evaporation causes the ore to be deposited in lumps, from the size of a shot to five hundred pounds weight. From the bottom of ponds these lumps can be raised with tongs, like oysters. In either form the large amount of vegetable matter which this ore contains makes the melted iron reduced from it exceedingly fluid, so that it runs into every nook and cranny of the casting mold, and reproduces it with sharp and precise outlines. When bog ores can be procured to mix with other iron ores, they produce a highly beneficial effect in the running of the furnace and quality of metal turned out; though, as a rule, they will not yield forty per cent. of metal. The pig metal obtained from them is so brittle that it breaks to pieces on being dropped on hard ground. Its weakness is in part due to its containing phosphorus, arsenic, etc. When taken from swamps, the workmen often throw into the cavities loose earth, leaves, brushes, etc., which, often within eight years, leave behind them fresh deposits of ore. The most noted places of supply for bog ore in this country are: Monmouth county, New Jersey. Piscataquis county, Maine and Snow-hill, on the eastern shore of Maryland. In the early part of the century much was obtained from the ponds of Plymouth county, Mass., and from Egg Harbor, New Jersey.

THE ALPINE FLORA.—Mr. John Ball, an English botanist of much repute, has had a passion from his youth upward for the scenery and flora of lofty mountains, and has passed many a day botanizing in the Alps, the Carpathians, the Pyrenees and the ranges in Spain. A memoir just published by him points out the curious fact that a close affinity exists between the Alpine flora and those of the mountains in Northern Asia, and this notwithstanding the vast interval of space that divides them and the wide differences in their climatical conditions. In the Altai range, forming the southern boundary of Siberia, fully one-fourth of the Alpine species are present. This is the more remarkable, because in the Caucasus, which is only one-third the distance of the Altai range from the Alps, and has moreover a more favorable climate, a smaller proportion is found. Mr. Ball relates that some twenty years ago he started from the Eggish-horn in the Alps with an ill-defined intention of reaching the uppermost end of the great glacier of Aletsch, the vastest field of snow in Europe, and of looking down on the pastures of the Wengern Alp from what is now called the Jungfrau Joch. The sun that day was hot, and the snow into which he sank at every step was soft and pasty. The great ice river is many leagues long, and has a channel two or three miles wide. Just at the point where the two great tributary streams join the main current, there was a steep slope clear of snow, and by following the track of some chamais, Mr. Ball found his way to the base of it, and made the ascent to a range of projecting rocks, which were about 10,700 feet above the sea. Along this slope, at a height of nearly 2,000 feet above the so-called jardin, near Chamouni, he gathered over forty species of plants in flower. This incident shows how extensive is the glacial flora, and how much labor is necessary before a complete enumeration of it can be made.

TELEGRAPHING WITHOUT WIRES.—Professor Loomis continues his experiments in the mountains of West Virginia to demonstrate the theory that at certain elevations there is a natural electric current, by taking advantage of which, telegraphic signals may be sent without the use of wires. It is said that he has telegraphed eleven miles by means of kites flown with copper wires. When the kites reached the same altitude, or got into the same current, communication by means of an instrument similar to that of Morse was easy, but ceased as soon as one of the kites was lowered. He has built towers on two hills about twenty miles apart, and from the tops of them has run up steel rods into the region of the electric current.—*Journal of the Telegraph.*

EYE DYEING.—"A learned German doctor," says a Paris paper, "has discovered a means of dyeing the eyes of animals in general, and of man in particular, any color that he pleases. He is accompanied on his travels of propagation by a dog with a rose-colored eye, a cat with an orange-red eye, and a monkey with a chrome-yellow eye. But the most curious specimens of his art are a negro with one eye black and the other blue, and a negress with one eye gold-colored and the other silver-white. The doctor says the process of transformation, far from injuring the sight, strengthens and improves it."

drift running north from No. 2 raise was advanced 8 ft
since last report through rich ore; the pay cube is raising

Having all the necessary appliances and long experience the proprietors of this shop are prepared to do all kinds of work, large and small; and their facilities are such that they will be enabled to make stationary and compound engines, quartz crushing and amalgamating machines, flour, sugar and sawmill irons, etc., at low figures.

BELMONT DISTRICT.
BELMONT.—The last report in the *Courier* says: The drift running north from No. 2 raise was advanced 8 ft since last report through rich ore; the pay chute is raising

Pliocene Man.

An interesting review in *Science News*, by Dr. Charles C. Abbott, of Prof. J. D. Whitney's chapter on "Human remains and works of art of the gravel series," is of local interest, inasmuch as it refers to discoveries in the auriferous gravels of the Sierra Nevada of California. Dr. Abbott says: Without doubt, the memoir by Prof. Whitney is the most valuable and interesting contribution yet made to the subject of American pre-historic archaeology. Not only has the topic great interest in itself, but this phase of it has an additional interest, because a portion of the evidence he brings forward has been subjected to much adverse criticism, not only by men of some scientific attainments, but by the popular secular and the biased religious papers of the day. The author, however, effectually disposes of all objections, as we think, and clearly demonstrates the correctness of the conclusions he drew, years ago. While being occasionally hinted at in various ways, these conclusions have never been published *in extenso*, until the appearance of the present volume.

We shall give in briefest outline the character of the evidence which Prof. Whitney here produces; it does not stand alone, but supplements and, we believe, confirms the indications of Tertiary men, both of Europe and Eastern North America. In his introduction the author remarks, that "gradually the evidence has accumulated from widely separated regions, until the idea of prehistoric man has become familiar to geologists." He then asks, "How far back can man and his works be traced?" The memoir supplies an answer to this question, so far as it relates to California. Any one who has spent days and weeks in searching for fossils or stone implements in gravel deposits, can testify how discouraging such work is. Millions of pebbles are to be glanced at and overturned, and often there is nothing but millions more to look at, when the surface of a bluff has been removed. In California, where the hydraulic method of attacking the gravel deposits is almost wholly employed, there is still less chance of finding objects of interest than there was in the older method of tunneling. Whether of bone or stone, traces of man subjected to violent displacement by streams of water are pretty sure to be destroyed or again buried by the rapid overturning of the gravel beds.

Much of the material on which Prof. Whitney bases his paper has been collected by Mr. C. D. Voy, and is now in the museum of the University of California. This material has been gathered principally from Mariposa, Merced, Stanislaus, Tuolumne and Calaveras counties. In Mariposa county stone implements and mastodon remains have been found intimately associated, at a depth of 12 feet. Much of like nature has been found in the two counties next referred to, while Tuolumne county is particularly mentioned as a region more prolific in human remains and prehistoric works of art than any other in California. This evidence of early man has been very carefully sifted by Prof. Whitney, and it appears that the fact of the remains being really found in such positions as to indicate great antiquity is fully demonstrated.

Calaveras county is more fully treated of, as the evidence is of somewhat different character, and has given rise to much discussion. "We now come," says Prof. Whitney, "to a county where occurrences of human remains do not seem to have been as frequent as they were in the adjacent Tuolumne, but where one specimen has been obtained which has excited more interest than all the others put together, and which is popularly believed to be the only instance of the kind which has been met with in California. A perusal of the following pages will, however, it is thought, satisfy the reader that the belief of the existence of man in that region previous to the cessation of volcanic activity there, is not by any means supported by one item of evidence alone." The history of this "one item," the now celebrated Calaveras skull, is then given in minute detail. Suffice it here to state, that it was found at a depth of 132 feet, and exhibits many peculiarities which tally with the statements of the finder, and are conditions which could only exist in a cranium found as this specimen is said to have been. This alone, as is most fully demonstrated by Prof. Whitney, should satisfy any one disposed to question the truthfulness of the statements made by the gentleman who found the specimen. Were nothing else ever to be found, there is in this Calaveras skull, as we believe, all that is necessary to demonstrate the existence of Pliocene man in California; but Amador, El Dorado, Placer, Nevada and Butte counties have all yielded corroborative evidence. As Prof. Whitney remarks, "the passage from Pliocene through Post-pliocene, if such a division can hereafter be maintained in this region, has been a gradual one, and some of the Pliocene animals have certainly lived close up to the recent period. That a portion of the human remains and implements described in the preceding pages are as old at least as Pliocene, it seems hardly possible to doubt."

"The discoveries in California, India and elsewhere seem clearly to indicate that the human race must have existed, over a large portion of the world at least, for an immense period of time, in the primitive condition, that is, at the

lowest possible stage of humanity—civilization it cannot be called. So far as California is concerned, the evidence all points in this direction. The implements, tools and works of art obtained are throughout in harmony with each other, all being the simplest and least artistic of which it is possible to conceive. Whether found in the strata under the basaltic lava, or above, at any point in the detritus, we always recognize the same type."

The conclusions of Prof. Whitney's volume are as follows:

"Finally, as the summing up of the discoveries and investigations made by the Geological Survey in California, we have:

"1. The clear and unequivocal proof beyond any possibility of doubt or cavil, of the contemporary existence of man with the mastodon, fossil elephant, and other extinct species, at a very remote epoch as compared with anything recorded in history.

"2. That man, thus proved to be contemporary with a group of animals now extinct, did not essentially differ from what he now is in the same region and over the whole North American continent.

"3. That there is a large body of evidence, the strength of which it is impossible to deny, which seems to prove that man existed in California previous to the cessation of volcanic activity in the Sierra Nevada, to the epoch of the greatest extension of the glaciers in that region, and to the erosion of the present river canyons and valleys, at a time when the animal and vegetable creations differed entirely from what they now are, and when the topographical features of the State were extremely unlike those exhibited by the present surface.

"4. That man existing even at that very remote epoch, which goes back at least to the Pliocene, was still the same as we now find him to be in that region, and the same that he was in the intermediate period after the cessation of volcanic activity and while erosion of the present river canyons was going on.

"5. That the discoveries in California and those in other parts of the world, notably in Portugal and India, present a strong body of evidence going to prove the existence, during an immensely long period, of the human race in its primitive condition—that is to say, in the simplest and rudest condition in which man could exist and he man.

"6. That, so far as we know, there is no evidence of the existence of any primordial stock from which man may have been derived, so far back at least as the Pliocene. Man, thus far, is nothing but man, whether found in Pliocene, Post-pliocene or recent formations."

That some of these conclusions, here so positively stated, may be modified by future discoveries, is highly probable. Especially as to the discovery of some "primordial stock," do we think this to be the case. That such stock once existed is necessarily true; that all trace of it has vanished is improbable; and not earlier than the dawn of the Pliocene is it necessarily needful that one should go to seek for such traces. The Pliocene epoch was not a matter of a few years, and what the formations of that age, in other continents, may contain that shall throw light on man's origin, have yet to be gathered. When the Pliocene strata of Africa and Asia have been carefully examined, and they are found to contain no traces of man more primitive than those of California and elsewhere, then it will be proper to expect that such traces will be found in the Miocene. That unquestionable traces of the missing link are now resting in some tertiary deposits, we have not the shadow of a doubt.

RIVER SURVEYING PARTY.—The boat known as "Noah's Ark," which was hauled upon the sands across the river opposite Tehama last Saturday and put upon a temporary dry dock for repairs, was again launched Wednesday last. Prof. Le Conte with 16 men are surveying the river and taking soundings, for the purpose of getting exact information where the channel is choked either by snags or sand bars. Their boat contains the sleeping apartments for the crew and kitchen and dining room. They will probably be two months on the river before reaching Sacramento city; they are now a few miles below here examining the rapids by the island. In some places in order to give sure channels all the year round, Prof. Le Conte said it would be necessary to build dams and gates. The work is a good one and we hope their report will be such as to secure the appropriation necessary to do the work required to open this natural highway.—*Tehama Tocsin.*

FIRE PRODUCING FROST.—A few days since, while observing the action of his new absorption refrigerating machine at Ruppert's brewery, Ninety-second street and Third avenue, New York city, Mr. T. L. Rankine casually placed a lighted candle against the expansion pipe leading from the liquid receiver. His intention was to melt the frost from the pipe; but to his surprise the effect was quite the opposite, frost forming within the flame much more rapidly than on other portions of the pipe. He afterward observed in the cellar he was refrigerating that directly over the burning gas jets the frost on the pipes along the ceiling was whiter and more abundant than elsewhere.

DURING the past 16 years, the Territory of Montana has produced \$153,000,000 in gold and silver, of which \$147,000,000 was in gold, making that Territory second only to California in the production of gold. There are now 20,000 quartz mills in the Territory.

Peculiarities of Alaska.

It would appear from the interesting letters to the *Bulletin*, written by John Muir from Fort Wrangel, Alaska, that the operations of nature's works in the formation of a habitable region, may be witnessed at the present time in the Territory of Alaska. In regard to the age of Alaska, Mr. Muir says:

From the universal distribution of the woods, one would be led, at first sight, to suppose that Alaska was an old country, considered with reference to its regeneration at the close of the glacial period, and that it had been long exposed to the disintegrating action of post-glacial forces, and had thus been covered with soil and then planted with trees. But, on the contrary, Alaska is a very young country, and its forests are mostly set on solid rock that had just emerged from beneath the ice-sheet. The existence of forests on so bare a surface is possible only in a wet and temperate climate like this.

As soon as the ice leaves the rock it is covered with moss, a deep, bossy blanket of it, in which the tree-seeds find lodgment, and grow and weave their roots together into a sod, so that one supports the other, and thus with a little anchorage here and there in fissured spots they are enabled to stand on steep slopes, even without any soil about their roots, or covering of any sort, save the damp mosses. On the very steepest and smoothest declivities the whole sod of trees will at times give way and slip down in a heap to the foot of the wall. But on the ruins another and another growth is built, until the whole is covered. One has only to go to the banks of the existing glaciers to see this forest work done.

Give to Alaska the climate of California, and these evergreen islands and shores would be treeless, sun-heaten rocks.

The forests are peculiar, and especially in Southeastern Alaska, their bulk is made up of three species of evergreens, all of which are of good size, and grow close together, covering almost every acre of the islands, however rocky, and the margin of the coast and the mountain slopes up to the height of about 2,000 feet.

The most important of these as to timber is the yellow cedar, or cypress (*Cupressus nultensis*), a truly noble tree, attaining a height of 150 feet, and diameter of from 3 to 5 feet. The branches are pinnate, drooping, feathery, dividing into beautiful light green sprays, like those of the California liliocedrus, but with finer foliage and more delicate plumes. The wood of this tree is undoubtedly the best the country affords, and one of the most valuable to be found on the whole Pacific coast. It is pale yellow, close grained, tough, durable, and takes a good polish; and to these qualities is added a pleasant fragrance, like that of sandal-wood. Some little goes to China, and is made into fancy boxes, it is said, to be returned to us for camphor wood. It is the favorite firewood of the coast region, but as open hearth must be closely screened with a framework of wire netting, as the wood in burning snaps, crackles and explodes, throwing out such a shower of glowing coals that there would be danger of fire without protection against them. The durability of this timber is forcibly illustrated by the fallen trunks lying in the damp woods. Many of the largest of them last for centuries, retaining even the delicate color and fragrance unimpaired. Soon after they fall they are overgrown with moss, in which seeds lodge and germinate and grow up into vigorous saplings, standing all in a row on the backs of their dear ancestors. As they grow larger they stand astride, sending their roots down and out on both sides like the straddling legs of a spider. And, after they have reached an age of several hundred years, the down-trodden trunk when cut into will almost always be found as fresh in the heart as it was when it fell. Decay goes slowly on from the outside, never commencing in the heart-wood, as far as I have noticed, though a good many of the living trees are injured by a fungus which produces a dry-rot similar to that found in thuja and liliocedrus. The species is found as far south as Vancouver Island, and is pretty generally distributed along the coast and through the islands, as far north as Sitka.

The white spruce, or Sitka pine (*Abies Menziesii*) ranks next in value as to its timber, while it is far more abundant than the first. Perhaps one-half of all the individual trees in southeastern Alaska belong to this species. In the heaviest portions of the forest it grows to a height of from 150 to 175 feet, with a diameter of from 3 to 6 feet, and in habit and general appearance resembles the Douglas spruce, so common about Puget sound. It is somewhat less slender, however, the branches cover a larger portion of the trunk, and the needles, radiating all around the branchlets, are stiffer and so sharp-pointed that the younger branches cannot be comfortably handled without gloves. The timber is tough, close-grained, white, and looks much like pine. It splits freely, and for general house building takes the place of pine.

The other species is the beautiful hemlock spruce (*Abies mertensiana*). It is more slender than its companion species, but nearly as tall, and the young trees are more graceful in habit, but the timber is inferior, and though very abundant is seldom made use of for any purpose where any other may be had. Of the other species found in these forests, but forming only

a small portion of the whole, the most noteworthy is the grand arbutus (*Thuja gigantea*), called red cedar hereabouts. It is distributed all the way up the coast from northern California, to about latitude 56°. From the soft, easily-worked holes of this tree the Indians make their canoes, some of them large enough to carry 50 or 60 men. A specimen nibbled out of a single log cut on the west coast of Vancouver Island is 60 feet long, 8 feet wide, and 4 feet deep.

Of pines I have seen only one species (*P. contorta*), a few trees of which, 50 or 60 feet high, may occasionally be found about the open edges of lakes and bogs. In the interior, beyond the mountains, it forms extensive forests. Cottonwoods, two or three feet thick, and from 40 to 60 feet high, grow on beds of flood-soil along the banks of the larger streams.

A fir like *Picea grandis* is common on the mountain slopes of the mainland. It is usually quite small however, seldom found to exceed a height of 60 or 70 feet, and the timber is of a very inferior quality. And up on the cold canyon sides along the banks of the glaciers, there is a very handsome little spruce like the Williamson of the upper forests of the Sierra. The only hardwood I have seen in Alaska is alder, maple, wild apple and birch—one species of each. The birch grows mostly on steep declivities well back in the Coast range in company with spruce and fir. The largest specimens are about 40 feet high and a foot thick. The other species are found only about the margins of the main forests. The trees are quite small, mostly about eight or nine inches in diameter or less.

It appears, therefore, that, with the important exception of the yellow cedar, timber trees for every use, as good or better in quality, abound in California, Oregon, Washington Territory and British Columbia, while those sources of supply are also nearer the markets of the world. And it will only be after those are exhausted on the more accessible portions of the coast that these grand Alaska forests will to any considerable extent be made available. Seward expected Alaska to become the shipyard of the world. So it may a century hence. In the meantime this supply will keep. These Alaska forests are not threatened with fire, or any other destruction dependent on the agency of man. They are too wet to burn. I have never yet seen a trace of fire in all these woods. The roots are set in a deep sponge of wet mosses, kept saturated by the abundant rains that fall throughout all the seasons, so that running fires are impossible here while the climate remains as it is. Beyond the mountains in the interior forests the conditions are different—less rain and greater summer heat—so that these woods are oftentimes scorched with fires as destructive as those that sweep the forest belt of the Sierra. In the vast region drained by the Yukon the principal tree, according to Kellogg and Dall, is the "white spruce" (*Abies alba*). I saw it on the Arctic divide, near the headwaters of the Yukon. It is an exceedingly slender tree, spire, erect and closely clad with short, leafy sprays, forming the sharpest and most arrow-like spires I ever saw in any forest. The tallest are about 125 feet high. Some of this inland timber may sometimes be made available for ship spars by floating it down to tide water; but centuries will probably elapse before this time of need will come.

The coast and inland forests of this south end of Alaska wear a grayish brownish color in the foreground, black in the middle ground and dark blue in the distance. The gray and brown is derived from lichens that depend from the branches, and from mosses that grow not only on the holes, but from large nest-like masses on the horizontal palmate portions of the main branches 50 or 100 feet above the ground. It is only where snow and rock avalanches have occurred that a bright grass-green is seen.

Landing almost anywhere to take a walk in these woods you have first to fight your way through a fringe of bushes tremendously intertangled—rubus, huckleberry, dogwood, willow, elder, etc., and a strange looking woody plant about six feet high, with limber, rope-like stems, and a head of broad leaves spread out horizontally like those of a palm. Both stem and leaves are covered with keen spires, so that it is impossible to grasp it anywhere without getting a multitude of thorns in the flesh. This is *Echinopanax horrida*, popularly known as the Devil's Cluh, and used by the Indians to thrash witches—the most truly diabolical thrashing instrument conceivable. It is the only plant that seems out of place here. It seems, rather, from its vine-like leaning stems and heads of ample translucent leaves, to belong to the tropics. Back in the shady depths of the woods the ground is covered with a thick felt of mosses, but little roughened with hushees of any kind, and not a track will you see of hird, beast or man on this yellow elastic carpet, not even those of the deer or bear that inhabit these woods.

A COPPER belt, some two miles long, and from 200 to 400 feet wide, has been discovered about the middle of the southern part of Maine, directly on the coast. Some 20 miles to the northward of this copper belt, silver has been found in flakes, masses and filaments. A shaft has been sunk some hundred feet deep, and it is reported that the ore increases in richness with the depth.

It is reported that tellurium, assaying as high as \$65,000 a ton, has been discovered about 25 miles west of Canyon City, Colorado.

THE ENGINEER.

Engineering Feats.

After ten years' labor, and after an outlay of more than \$6,000,000, the famous Sutro tunnel has been opened, and in eight hours it had lowered the water in the long drowned-out mines more than 100 feet, and rendered them accessible to work. The great Tehachipichi railway tunnel is near its completion. The great tunnel at Hoosac is in use. Captain Eads has received the indorsement of the United States engineer at New Orleans that he is entitled to half a million dollars for having completed his project of deepening the navigation of the Mississippi by a system of jetties that would keep the river open and insure its commercial standing. There are other equal schemes in progress, all of which are intended to relieve the transportation or assist the industry of the country. Now it is proposed to obviate the difficulties of Isthmian navigation by a railway capable of transporting the largest vessel from sea to sea, while various plans for tunneling or canalizing that impracticable strait are considered.

It would be easy to extend this brief catalogue of some of the great engineering feats of the country within the last few years, not the least among which is that which gives access to New York. But the instances which we have cited suffice. They show the grandeur of the attempts, their practical use, the enormous sums involved, the impediments met and to be met, and the success of American scientific labor. They are very interesting, because they are in the alphabet of a science whose calculus we do not know, and whose European parallels, shown in the Thames tunnel, in the St. Gothard and Mt. Cenis passes, in the Suez canal, in the projected tunnel between England and France, and in that from Spain to Africa, compel scientific notice everywhere. It is not singular that for so long a period Europe should have held the van in this department. The population there is denser, the commercial wants are much greater, the capital is more enormous, labor is cheaper, and political agree with industrial wants. Here, however, the schemes are scarcely if at all less gigantic, the costs are equal, the uses are not less, and coming advantages connect with present desires. The wonder is that our science ventures upon such essays, and is sustained by such capital; that such a great forecast is indulged in when the moment is unpropitious, and there is such a uniformity of success. The credit is reflected in equal proportions upon the ability which plans and the business which dares to execute.

And these are all engineering feats—feats of that very power which is to-day rendering the Delaware as navigable as the Thames or Mersey, which is boring through Eastern as well as Western mountains, and separating our peninsulas. Our advantages are being realized and our possibilities attained, so that when the century has closed we shall hold a far different position to the world, relatively and positively, from that which is now ours.—*North American*.

IMPROVEMENT OF THE CANAL SYSTEM.—The network of canals in France, which has already reached a high state of development, is about to be largely supplemented and improved. A law passed August 5th last sanctions a comprehensive scheme for the reduction of all existing lines to a uniform plan, and for the opening up of a large number of new canals. This law divides the existing waterways into main lines, which are placed under the exclusive management of the State, and branch or secondary lines, which may be opened and worked by private individuals or companies, with or without a State subvention. Article 2 fixes the minimum dimensions of the main lines (to which class all the existing canals of any importance may be said to belong), and enacts that all locks shall be at least 5½ meters wide by 38½ meters in length, with a water depth of 2 meters. The importance of the establishment of a uniform scale throughout the country can hardly be over-estimated when it is remembered that hitherto the canals have been cut with reference to local requirements only, so that the boats of one district were often unable to utilize the waterway of another, and the transshipment of goods under passage into smaller boats became necessary, involving much expense and loss of time. The wonder is that under such unfavorable circumstances the traffic has remained so considerable as has been the case. The law of August 5th not only provides for the improvement of canals already existing, but also decrees the institution of ten new main lines and eleven new subsidiary lines, the total expense of which are estimated at 930,000,000 francs. Among the new lines are a canal from Havre to join the inner system, a shorter route from the Belgian frontier to Paris, a canal from the Scheldt to the Maas, another from the Upper Marne to the Saone, and a line thence to Doube.

METAL STAGE CURTAINS.—While Wagner's "Nibelungen" was being performed at Munich, recently, the drop-scene took fire. Happily there was a metallic curtain which separated the stage from the auditorium, and this was immediately lowered. After some little interruption, the fire was extinguished, and the actors went through the piece in the midst of the charred remains.

USEFUL INFORMATION.

Brass.

Corinthian brass was said to be a mixture of gold, silver and copper, formed by the running together of statues, melted in the flames of the city of Corinth, whom it was burned by its Roman captors. It brought a very high price for generations afterward. The name "brass" was commonly applied among the ancients to what is now known as bell or gun metal, a mixture of copper and tin. The alloy of copper and zinc was known and used ages before the mixture of the latter metal was discovered; and it is even said that the use of brass was discovered before that of iron. A mass of zinc ore, mingled with charcoal and plunged into melted copper will yield the metal, which will be at once dissolved by the copper. This was the ancient process, the only one till 1781, and is still in use. Modern modes consist in melting the zinc and adding copper in thin strips, or in a fused state; or in melting copper and plunging into it lumps of zinc, held below the surface with iron tongues. At the temperature of melted copper, zinc is very apt to evaporate, and deep layers of fine charcoal or glass on top of the fluid metal, so much zinc passes off that chemical analysis alone can determine the proportion of each metal in the product. The usual proportion is a pound of copper to eight ounces of zinc. "Prince's metal," a beautiful yellow combination, contains equal weights of each ingredient. "Muntz's patent sheathing, or yellow metal," is made of about two pounds zinc to three pounds copper. Bath metal, Pinchback, or Manheim metal, is made of three or four ounces zinc to a pound of copper. The addition of zinc hardens and whitens the copper. Oreide is also a combination of copper and zinc in the ratio of 100 to 17. Brass can be precipitated from a solution of sulphurets of the two ingredients mixed with cyanide of potassium, by using a galvanic battery with a brass plate attached to the negative pole.—*N. Y. Mercantile Journal*.

Mineral Oils as Lubricants.

At a late meeting of the Railway Master Mechanics' Association of the United States, there was rendered a report of a committee appointed to examine into and report on the subject of lubricants. They recommended a good quality of natural earth oils as the best to use for lubricating machinery and journal boxes. It was less expensive, and of a better quality than other oils. When treated so as to reach 28° of gravity, it was found to work with perfect success, even on so sandy a road as the Lake Shore. It had been reported favorably on from Canada in the north to Kentucky in the south. A test of various oils had been made with the oil tester on the Lake Shore road; sperm, lard and tallow were used, and none of them were found to possess qualities which render their use advisable. In their experiments the committee used a machine the size of a regular axle box, and 50 drops were poured in at a temperature of 60°, and the wheel was allowed to revolve at a rate of speed equalling 35 miles per hour, until a temperature of 200° was reached. The length of time, number of revolutions and amount of friction were all noted and placed in the form of a table. Attention was called to the result obtained from tests with paraffine, which coats from 25 to 30 cents per gallon, and which has been used on railroads in preference to lard oil. Paraffine costing 25 cents, with which six experiments had been made, showed that 24 minutes were required to reach the maximum temperature, during which time it gave 11,685 revolutions; castor oil, costing \$1.25, which required 28 minutes to reach the temperature allowed, gave 12,946 revolutions; manufactured oil, A, B and C, costing 35 cents, 90 cents and 25 cents respectively, required 19½ minutes, giving from 9,285 to 9,653 revolutions; sperm and tallow required only 17 minutes to reach 200° temperature, with less than 8,000 revolutions.

CHEAP BLACK FOR WOOL.—The cheapest black for wool is obtained by treating the wool in a mixture of dilute sulphuric acid and dichromate of potassium, or of sulphuric acid, potassium dichromate, potassium bitartrate and copper sulphate, and subsequently dyeing with logwood. Reimann now proposes to use, instead of either mixture, one of chrome-alum and bitartrate with logwood. For the chrome-alum, the impure solutions of it obtained as bye-product in many manufactures may be used. The iron-alum in this process not only serves as an oxidizing agent, taking the place of chromic acid and copper sulphate in the first two mixtures, but also deepens the black by itself forming a compound with the logwood. The advantages of the new process are: (1) there being no chromic acid in the mixture, the wool is not oxidized, and remains soft to the touch; and (2) the black is a mixture of chrome and iron-black, and while free from the drawbacks of either, possesses the good qualities of both. Chrome-black is unaffected by acids, but is injured by alkali and exposure to light; iron-black has exactly opposite properties.

CAUSTIC ALCOHOL.—Dr. B. W. Richardson, of London, prepares this alcohol as follows: Take one-half fluid ounce of absolute alcohol in a two-ounce test tube. Set in a water bath at 50° F. Add gradually small cuttings of clean metallic sodium until hydrogen gas ceases to escape. Then raise the temperature to 100° F., and add a little more sodium, or until the gas again ceases to rise, stopping if crystallization occurs. Cool to 50° F., when the preparation thickens. Add one-half fluid ounce of absolute alcohol (for the strongest caustic to apply), or more, as needed for the use desired. Two parts of absolute alcohol will require one part of pure sodium to make the absolute sodium alcohol. The sodium alcohol is diluted, according to the end to attain, with absolute alcohol, and "can be used so as to cut like a knife," or so as to serve as a mild caustic, little more than a very sharp stimulant. Dr. Richardson considers one part of the sodium alcohol to one and a half parts of the absolute alcohol as the strongest caustic safe against causing hemorrhage, for vascular parts. The preparation will dissolve opium and nearly all substances soluble in alcohol.

A NEW DISCOVERY.—A German scientist, after years of study and experiment, has succeeded in obtaining a chemical composition by means of which a mirror image may be fixed and sold as a photograph. With this composition the mirror surface is painted, and the back part of the mirror receives also a coating of oil. The mirror thus prepared is held before the person who is to be photographed. The oil coating evaporates, and the likeness of the person remains in natural colors on the light surface. The image so fixed is brought into a bath and is exposed half an hour to the sun-light before delivery.

GOOD PASTE.—Herr O. Heim, of Grimmen, gives a recipe for marking a durable paste. He takes 20 grammes of wheat starch, and makes it into a stiff paste with a little cold water; then he pours 100 c. c. of boiling water all at once—not gradually—into this paste, and stirs it rapidly. A little carbolic or salicylic acid is then stirred in, and a paste is obtained which will keep indefinitely (or at any rate until it dries up) in a cool place. Care must be taken to have the best starch, as good paste cannot be made with the inferior kinds.

GOOD HEALTH.

Comparative Mortality of Rich and Poor.

Dr. Drysdale, Senior Physician to the Metropolitan Free Hospital, called attention in the Social Science Convention, recently in session at Manchester, England, to the comparative mortality of rich and poor. How came it, he asked, that in Great Britain, in the face of improvements in every direction in the domain of hygiene, there still remains a death-rate in our cities ranging from 30 down to 20 per 1,000 of the population annually? If we look to one city, London, for instance, we find that, with all the advances recently made in that wonderfully healthy city, the death-rate was actually 22.2 per 1,000 in 1856, and in 1876 a little higher, or 22.3. Many persons have asked, on reading such figures, "What is the use of medical science if it can effect nothing more than this?" The real cause of the non-effect of the countless hygienic advances was indigence. Villermé, the French medical writer on hygiene, found some 30 years ago, that persons over 40, if in easy circumstances, had a death-rate of only 8.5 per 1,000, whilst the mortality in a similar class among the poor was more than double, or 18.7. He also showed that in Paris, there died, between the years 1817 and 1836, 1 inhabitant in 13 in the 13 arrondissements, chiefly inhabited by the poor, and but 1 in 63 in the second or rich quarter.

The most accurate statistics ever compiled on this subject are from the pen of C. Ansell, Jr., entitled, "Statistics of Families of the Upper and Professional Classes," published in 1874. The author collected information concerning 48,044 children of the well-to-do classes in England and Wales, including members of the legal, clerical and medical professions, as well as that of the nobility and gentry. He found, from these inquiries, that in the first year of life, only 80.45 per 1,000 deaths occurred among the infants of the easy classes in this country, as against 149.49 among the children of the general population. The death-rate then, of the children of the comfortable classes being 80 per 1,000 in their first year, we found it to be 240 per 1,000 in cities like Manchester and Liverpool, and as high as 300 in the poorer quarters of our cities, and in Berlin actually 500. From one to five years of age, 46.84 children of the upper classes die of 1,000 born, and as many as 113.69 in the general population. During the remainder of early youth from 5 to 20, the difference is not marked; but 65.47 per 1,000 deaths occur among the richer classes, as against 74.04 in the general public. Between 20 and 40 there die among the richer classes, 125 per 1,000, and 124 among the general population; and between 40 and 60 there die 147 per 1,000 among the rich against 168 among the general population. The general result of this calculation shows that the average age at death is among the rich in England and Wales 55 years, whilst it is not probably 35 among the artisan class; so that Mr. Ansell estimates that in one

year there die in England and Wales under the age of 60, 368,179 persons, which figure should only have been 216,048, if the population had all been in easy circumstances. Thus some 142,000 deaths annually in England and Wales are due to indigence. Health is very imperfectly secured in the lower grades even of respectable citizenship. The public registers have demonstrated that mortality and diseases diminish with every rise in the scale of wealth.

The Physiology of Recreation.

So much, then, for the meaning of recreation. The next point that I shall consider is the physiology of recreation. It may have struck some readers as a curious question, why some actions or pursuits should present what I may call a recreative character, and others not. For it is evident that this character is by no means determined by the relief from labor, which these actions or pursuits secure. A week on the moors involves more genuine hard work than does a week in the mines, and a game of chess may require as much effort of thought as a problem in high mathematics. Moreover, the same action or pursuit may vary in its recreative quality with different individuals. Rowing which is the favorite recreation of the undergraduate, is serious work to the bargeman; and we never find a gardener to resemble his master in showing a partiality to digging for digging's sake. If it is suggested that it is the need of bodily exercise which renders muscular activity beneficial to the one class and not to the other, I answer, no doubt it is so partly, but not wholly; for why is it that a man of science should find recreation in reading history, while an historian finds recreation in the pursuit of science, or why is it that a London tradesman should find a beneficial holiday in the country, while a country tradesman finds a no less beneficial holiday in London? The truth seems to me to be that the only principle which will serve to explain the recreative quality in all cases is what I may call the physiological necessity for frequent change of organic activity, and the consequent physiological value of variety in the kinds and seasons of such activity. In order to render this principle perfectly clear, it will be necessary for me very briefly to explain the physiology of nutrition.—*George J. Romanes, in Popular Science Monthly for October*.

ACTION OF SEWER GAS ON LEAD, ETC.—The sanitary inspector of Dundee, Mr. T. Kinnear, has watched the effect of the gas on portions of the zinc eaves of buildings where it was striking on the under part, and found, in the course of a couple of years or so, pretty large holes eaten completely through, showing that material could not long withstand the effect of the gas. Lead is, of course, more durable than zinc, but the difference is only a question of degree, as shown by the fact, in not a few of the water-closets repaired by the officers of the department during the year, small apertures were found in the main vertical lead pipe, and in the cross or horizontal one leading from it to the trap of the closet various perforations were found on the top, indicating clearly the operation of foul air from the drain. Lead traps and soil pipes from water-closets, baths and fixed basins are all subject to wear and tear; but the traps, being burdened with the additional strain of barring the passage of sewer gas, do their work less efficiently, and for a much shorter period, than they are generally credited with, hence, the necessity for proper ventilation and occasional inspection.

NEW CLOTHING MATERIAL.—A Berlin inventor has patented a new kind of cloth, which consists principally or entirely of sponge. The sponges are first thoroughly beaten with a heavy hammer, in order to crush all the mineral and vegetable impurities, so that they can be easily washed out. They are then dried and pared, like a potato, with a sharp knife, the parings being sewed together. The fabric which is thus obtained is free from all the danger which sometimes arises from the absorption of poisonous dyes into the system; it absorbs without checking the perspiration, so as to diminish the danger of taking cold; it is a bad conductor and therefore helps to maintain a uniform surface temperature; it can be more readily cleansed than the ordinary woolen garments; its flexibility diminishes the liability of chafing; the ease with which it can be employed in shoes, stockings, drawers, undershirts, hat-linings and other articles of clothing seems likely to make it especially useful as a protection against rheumatic and pulmonary attacks.

A NEW THERAPEUTIC AGENT.—A new method of treating cancerous growths, tumors, etc., consists in subjecting the parts to a stream of hot, dry air. This is proposed and has been successfully applied by Dr. G. A. Keyworth, of England. By means of a foot-bellows he caused air to pass through a glass vessel containing calcic chloride, then through a heated iron tube, and thence directed the hot, dry air against the surface of a cancerous sore. The treatment was continued for an hour, the effect being to relieve the pain and cause the parts heated to shrink and dry up very considerably. It is believed that this new method will prove valuable when proper appliances are employed to maintain and direct the supply of the air.—*Scientific American*.

The Week.

The line of demarcation between skilled and unskilled mining is gradually becoming obliterated by the spread of information which is rapidly placing mining upon a scientific basis. A reference to our "Mining Summary" for the week will show continued activity in prospecting, and with good results springing from a more accurate knowledge of indications. A railroad to Bodie is on the cards, and it goes without saying that means of transportation will add an impetus to the mining interests which the resources of Mono county justify. The mines of Alaska are becoming important, from the fact that closer investigations of the mineral resources of that Territory have been made. Important results are said to have been obtained in Nevada county by the Gould process of oxidation and amalgamation at Meadow Lake, and by the Smith process at the Murchie mine, at Grass Valley, which is the last aspirant for favor in the way of reduction of sulphurets by amalgamation. The hydraulic mines are preparing extensively for the coming rains, which promise to be sufficient for satisfactory working.

Our mines are exciting the attention of English capitalists who continue to seek investments. Our English exchanges are disposed to favor the investment, although warnings are uttered that there must be fair dealing. We are induced to believe from present developments that the days of bare-faced swindles in mines are over.

The labors of the Land Commission have continued, and if there be no other result than to arrive at the bottom facts regarding the debris question and general land questions, its labors will not have been in vain. Clearer ideas in regard to the legal features which should cover these important points are being made manifest; and if a millennium cannot be predicted in the near future, we may hope that the reign of common sense, its forerunner, will soon assume the scepter.

The Element of Shrewdness.

The practice of driving sharp bargains may certainly be regarded as a universal peculiarity of men in their business ventures. History abounds in instances of the sharpest dickering among all nations, barbarous as well as civilized, from the bargain and sale of a kingdom down to common transfer of a horse, and the shrewdness of either party to the transaction is gauged by the advantages derived from the result of the exchange or transfer. Dispossessed of trickery or swindling the element of shrewdness is a laudable characteristic of any business, but when accompanied by intents and appearances calculated to deceive the unwary the transaction no longer deserves the nomenclature of shrewdness, but becomes a downright fraud; and instead of redounding to the credit or enuring to the benefit of him who perpetrates it, a positive injury is accomplished which affects the whole range of subjects embraced by the transaction. An individual once swindled, if of a confiding nature, realizes an entire change in his disposition, and condemns not only the swindler, but all others in the same line of business, as well as the business itself. The reason is all men who have money to invest are not philosophers, and do not care to investigate the morality of future transactions. The more any particular business depends upon mutual confidence, the greater will be the injury caused by any deception. In staple articles the defrauded party has his remedy by forcing the defrauded to exchange for a satisfactory one, or he can purchase elsewhere, and to that extent lessens the business of the deceiver, and thus the individual only is deprived of his trade. But where the very nature of the transaction lies in its qualities as an apparently good investment, every deception is attended by a loss to the whole of that class of business and effects the whole of a community engaged in it. Of this nature is the mining business. Men do not invest in mines through necessity, but only because it is believed they will make good investments, and every mining swindle, on this account, affects the whole region where the oreless mine is located. The vendor gets away with his swag, and the vendee is left remediless, a victim of false representations and misplaced confidence. The individual who fails to give another a *quid pro quo* for his money is too often regarded as shrewd in a degree proportioned to the amount he gets as the price of his dishonesty. Looked at from a purely human point of view the transaction possesses neither shrewdness nor business tact. Shrewdness and business tact look to future advantages as well as to present gains, and to kill the goose that lays the golden egg is so silly, though common a proceeding, as to merit not even the censure of a schoolboy's intelligence.

The London Mining World and Engineering Record of October 4th ult., gives utterance, under the heading of "American Mines," to some solemn truths which it were wise for every present and prospective American miner to ponder, especially at this time, when the course of conduct to be pursued by them may make or mar the future of our mining prospects in general. We have the mines of gold and silver against which the world cannot compete, but we need the capital to work them. With millions in sight, so to speak, millions more in cash are required to utilize the glittering metal. This cash is capital, and coming from whatever source it may, it deserves at least to be met with a spirit of honesty and fairness, or else the scepter of empire so long expected will be still longer in coming this way. So far as regards English investors, the past has demonstrated their desire to aid in the development of our mineral resources. They do so, of course, for the profits to be realized. Can they or any other capitalist be expected to invest for any other reason? To show what has been done for their encouragement we have only to cite the Emma, the Flagstaff, the Last Chance, the Tecoma, the Utah, and others that might be named. The results of these swindles have nearly given the *coup de grace* to the floating of any more mines upon the English market. If English investors are to be induced to contemplate American mines again, and we presume we may say that there is no desire to prevent them on our part, they will only do so under very altered conditions to those which formerly prevailed. As our exchange says:

"They are not indisposed to face the risks of mining in America any less than they are those which attend that operation here, but they will not certainly allow themselves to become the dupes of unscrupulous vendors, who, when they have got their plunder, leave the ship to its fate—if, indeed, they do not try to scuttle it as their parting act. There seems to be a tacit understanding on this side of the Atlantic (of which the Americans would do well to take heed), that for the future closer bargains must be made with vendors than heretofore, both as regards purchase-money and the throwing of their shares upon the market. Under the old system the vendor received a considerable sum in cash, and then his sole object was to keep up the price of the shares in the market until he had disposed of those he had obtained as part of the purchase-money. Then, as we have said, he left the concern to its fate. Sometimes he was not even so kind as this, but afterward hampered its proceedings, attempted to upset

its title, and even to regain possession, by the most unscrupulous means, of the property for which he had been paid so well. As a matter of fact, one or two, or perhaps even more of these individuals are to-day in actual possession of the properties they once sold, and probably when the times are favorable will attempt to float them again under different names and with their own identity carefully concealed."

It may be a "good joke" to circumvent foreign capitalists, but the joke is altogether of too practical a nature to be useful. We have more good minees than can be fully developed for a century to come, and there is, therefore, no occasion for throwing poor ones on the market. Let us be careful and make no mistakes.

Hints to Miners.

The disadvantages under which many of the mining fraternity labor are frequently aggravated, not only by the lack of proper appliances to aid in his prospecting, but also in the absence of useful hints, which, drawn from the experience of many, should be collated in a compact and serviceable form. While it must be admitted that experience came before books, yet we must likewise admit that much information can be gathered from the results of experiences undergone by others, and many hardships and mistakes avoided. These results are gathered from books containing the fruits of what others in the same field sought to accomplish, and succeeding, pointed out a beaten path for others.

We select from "The Explorers', Miners' and Metallurgists' Companion," by J. S. Phillips, M. E. (which work has, under the private publication of the author, already reached its third edition), a portion of Chapter IV, upon the peculiar kinds of the primitive and secondary rocks, which concern miners, as being most congenial for rich veins; and what formations should be avoided. As illustrating what we have just said in relation to making available the experience of others, Mr. Phillips says that the extensive and profitable mines throughout the world have been found near the junctions of the various primitive and secondary strata, frequently in both. Other collateral causes must be also present to create the fissures and supply them with the several elements, and their solvents and precipitants, or minerals will not be precipitated therein.

Granite proper, with the three ingredients of quartz, feldspar and mica, is the primitive rock of Cornwall and many other noted mining regions, but in this country syenite, composed of quartz, feldspar and hornblende, appears to take its primitive positions, and where the tilted and metamorphosed secondary rock are also suitable, a great many very good silver mines have been found. These are not the only primitive formations congenial for mineral. As even true syenite is comparatively rare, the experience of the author in mineral-bearing primitive mountains, where the "country" or "bedrock" formation has not been produced by subsequent volcanic invasion, is, that if the rock is largely composed of feldspar, it is quite immaterial whether mica or hornblende is present, even the quartz may be entirely absent; provided also the rock has been sufficiently crushed and disrupted into joints by lateral pressure, to produce the necessary metamorphism for such deposits.

Now, the question arises, what are the additional appearances, modifications and transformations to be sought in these strata? The answer is that there are five very valuable indications; the first and most important being broken ground, or partial disruption, disintegration and decomposition of the stratum, which show that sufficient force has been in action for the creation of veins and for the shattering of the surrounding bedrocks to admit the free percolation of mineral waters as well as greater freedom for the decomposition of those rocks which may contain their precipitants. The centers of extensive primitive ranges are naturally very compact and water-tight, for which reason veins and minerals are seldom found in such elevated and primitive positions.

A second characteristic of mineralized districts is where the reefs of various rocks interlace and distort the primitive, transition and secondary formations by curvatures, shifts and slides, particularly when they range at varying angles and give evidence of different ages of such disruptions.

In the third place it is an invariably favorable sign for gold, as it is sometimes for silver, when the upheaved talcose, micaceous and argillaceous clay slates are much folded and tilted, even to the vertical for long distances, from their originally horizontal position, and when the very lowest foothills and oceanward flats show the presence of the oldest fossils of salt-water shells.

For a fourth indication, a moderate amount of the stains from the oxide of iron, generally disseminated throughout the stratum and mixed with the sulphurets of iron in and near the vein, are excellent guarantees for the presence of nearly all of the metals and metallic minerals, many of which are never found away from its influence or out of its company.

The fifth and last indication is the most difficult to describe, although as much heeded by the miner as is the soil by the farmer. It consists in what the miners designate as "kindly ground," "sugary spar" and "rotten ripe,"

the reverse being "ugly, unkindly ground," "hungry country spar" and "dried-up ore." It is, as the author says, "a peculiarly congenial and prolific stratum, and a corresponding generous, maternal nature of the quartz from the veins, as well as a fresh, pregnant ripeness of the minerals themselves, as if but just arrived at complete etrength, ere they are again dispersed by nature's solvents."

In prospecting it is inadvisable to go far away from the junctions of the transition or secondary with the primitive rocks, or to penetrate the interior of the more igneous volcanic regions.

Porous volcanic bedrock should be avoided for deficiency of veins and paucity of minerals, the few exceptions of metal in such a formation only prove the rule. Modern carbonates of lime and magnesia and clay slates that enclose well-defined and comparatively recent shells seldom produce veins with sufficient minerals to pay for extraction; excepting, however, rare pockets of silver, and the ores of lead, iron, coals, etc.

Another and important point to be regarded is the avoidance of too close proximity to extensive deposits of mineral, the property of others, as the largest bunch has its limits; and sufficient space must remain for the accumulations of the metallic elements or precipitants before another considerable body of ore can be deposited. It is generally better to go a few hundred feet, and often miles away from, than to mine in close proximity thereto. The history of great discoveries has too frequently shown a debit balance from each district by this very indiscreet practice.

The miner must always remember that deposits fall much oftener than they continue rich, and that very many blanks must be expected for one prize. It is well not to be over sanguine, but rather to seek for defects in the formation and poverty in the mineral deposit before becoming too certain about the value of any particular "find." It is true that there are no certain indications in some of the secrets of nature, but the rules that have been laid down may be considered as relatively true, and if carefully followed with good judgment, for which there can be no rule, a certain amount of satisfactory success will attend the effort.

Stability and Prosperity of Mining.

Any business that is not remunerative cannot long be sustained or kept in operation. Among all the industries of the United States gold and silver mining have become so well established upon the base of profitable investments, that their permanency is no longer a matter of doubt. This industry is now regarded as a desirable one to engage in, and is destined to develop more and more evidences of reliable stability and continuous profit. We find that new investments are being made in gold and silver properties, and what is a still more favorable indication for the future welfare and solidity of mining operations, these investors are exercising a judicious caution before embarking in any mining enterprise. Carefully considered and cautious investments cannot fail of success. Where some make mines profitable, others are sure to follow in their footsteps. There is one great advantage in the business of mining for gold and silver, and that is, no matter how productive the mines may be, there is always an unlimited demand for their product, and there is no need of apprehension that the market will be overstocked.

Mining investors are appreciating the fact that it requires both labor and capital to place a mine in a working condition. They also know that economy is necessary in conducting the business. They do not therefore enter into the business with the same degree of speculation that for so long a time rested as a blight and evil upon mining. They go into it with a determination to make it a success. Under such a system, as before stated, mining must become a permanent and stable industry. The extravagant outlays that have so frequently attended mining, and that have conducted so greatly to the failure of conducting it, will not, under the new system, be incurred. These absurd expenditures will no longer be indulged in, for the lessons taught by past experience are not so readily or speedily forgotten. The rigid economy that will supersede the hitherto extravagance, will lead to a profitable result. Then when the mine is sufficiently developed to show ore enough to pay for the building of the needed improvements, it will be only a question of time and skillful management as to when it shall yield a profit to its owners and return to them the capital invested in the enterprise. Under this regime, mining is rapidly assuming its true position among the industries of the age—that of a permanent calling, and one of undoubted profit. With such a reputation, it will no longer be regarded as an uncertain and chimerical adventure, which detracts from the commercial credit of those engaged in it, but it will redound to their financial status as being connected with the most lucrative and vital business known. The dawn of a better era in mining is evidently now the precursor of an unexampled condition of prosperity in mining.

A GENERAL subscription will be taken among the Catholic temperance organizations of Great Britain for the relief of the distressed in Ireland.

The Influence of Water in Mineral Veins.

[Written for the Press by S. P. LEEDS.]

Any light, even if but feeble, that can be thrown upon the principles which govern the formation of mineral veins and the deposit of the metallic ores in them, will be interesting, and may be valuable. If these principles were more thoroughly understood, such knowledge would greatly assist the practical miner in his determination whether to prosecute or abandon a lode. It would prevent a loss of time, labor and capital, which too frequently occurs in mining explorations. It would advance mining interests by leading to the prosecution of only really good veins.

There must be fixed natural laws which prevail in the formation of veins, for they cannot be the result of fortuitous circumstances. The uniformity of their phenomena is too obvious to be the result of accident or chance. Whatever those laws or principles are, they are still in activity; the veins have not lost their vitality. The process of solution and deposition is still going on. We witness this on the walls of copper lodes, where the deposition of the salts of copper are continually forming. We have instances of it in old silver mines that have long been flooded with water, by the deposit of silver upon the wood-work and sides of the tunnels or shafts. It is evident in the deposit of crystals of iron pyrites in similar situations. Nature never wastes material. Time does not appear to enter as a necessity in her workings, in an economical sense. The growth of a crystal may occupy centuries. When it is constructed its constituents are chemically adjusted—balanced with precision, and not a needless atom is contained in its structure.

All veins give proof of the action of water. Even the dry ones show that their dryness has not always existed, but that they have been filled with water at some previous period. A mineral vein could not exist unless water had been contained within it at some time during its formation.

What is termed the water-level varies in different portions of the same lode. The tightness of the vein, its contraction or expansion, may influence the passage of the water through it; and the looseness or the solidity of the adjoining rock may flood it in some places and keep it back in others. When, however, the water-level is reached, as a general rule, the ore becomes more compact and their character becomes more permanent.

Perhaps the opinions of others may not be out of place here.

When a band of rock is found very dry, and of a close crystalline grain, it is unfavorable to produce mineral.—E. Hopkins' "Geology and Magnetism," p. 95.

I was informed by an intelligent proprietor of mines in Cornwall that these thin cross-courses invariably displace the veins, and hold up the water on one side of the vein; but it is most worthy of notice that a vein which is rich in ore on one side of this flun will be poor on the other. Is this connected with the flun holding up the water?—"Bakewell's Geology."

This abundance of water, although occasionally very troublesome, is one of the very safest signs of persistence in depths yet unattained. It is extremely desirable.—O. M. Leiber, Geol. Rep. South Carolina for 1857.

The entire surface of the globe, to the depth of one mile from the level of the ocean, contains upward of 60% of water. The active principles of minerals, vegetables and animals cannot exist without water.—London Mining Journal.

Any cause which keeps up the supply of water in a vein must inure to its benefit, because they yield to the water a solution of metallic salts, which are deposited within the vein.

The miners both in Wales and Derbysire, maintain that wherever there is a depression in the strata, and they dip on both sides toward the vein, in such situations the richest veins occur.—"Bakewell's Geology," p. 357.

In pursuing the inquiry, "What influence does water hold in mineral veins?" it will be examined in the varied phases of—1st, its property as a solvent; 2d, its mechanical action; 3d, its electro-magnetic bearing; and 4th, its chemical power.

The Property of Water as a Solvent.

The solvent property of water is established beyond cavil. To what extent it is capable of acting upon metals or their salts in its passage through the crevices or pores of the adjacent rocks or the vein is not so completely determined. Still it is of sufficient intensity to produce a marked action upon all metallic salts, and in many instances upon the metals themselves. Some of the springs that flow to the surface are so fully saturated with mineral matter as to commence a deposit of it as soon as their waters meet the atmosphere. These deposits are so abundant, especially in the vicinity of thermal springs, as to raise extensive mounds around them which in some cases extend over many acres of ground. Such springs are confirmatory of the solvent power of water. The analysis of the water of the Rhine by Pagenstecher showed it carried annually out of Switzerland a quantity of solid matter in solution alone equal to a cube of 866 feet side.

When veins that have long been kept dry by

artificial means have been allowed to refill with water and remain so for many years, mineral depositions will be found to have formed upon the timbers. The presence of the water has renewed the activity of the natural forces acting within the vein, and its solvent properties have enabled it to carry in solution the metallic ingredients that it deposited. But more especially is this solvent power manifested when the water is impregnated with certain gases or with alkaline solutions. The oxides of the metals are most freely acted upon by such solutions, and their deposit is sure to occur under favorable conditions. Native and vitreous silver was found coating the wooden supports of the Dreyweier mine in Marienburgh, which had been under water 200 years, and was reopened in 1777. As the primitive rocks contain mors or less potash, the source of this alkali is readily accounted for. The presence of soda or lime in solution is also frequent. Should these alkaline waters also contain a chemical combination of sulphur they would act still stronger upon the oxides of metals with which they would come in contact.

All substances become dissolved in the course of time in the ordinary temperature of subterranean liquids. Sulphate of baryta, a substance common in lead mines, has been termed insoluble, although found in such a state as to leave no doubt of its being deposited from solutions.—Hopkins' Geol. and Magnetism, p. 89.

Hot springs and aqueous vapor are able to act very powerfully upon hard rock, such, for instance, as marble.—Bischof, on Heat of Globe, p. 26.

Additional testimony of the solvent power of

CAMP AT FLAMING GORGE, GREEN RIVER, UTAH.

water might be accumulated from geological writers, and from the experience which practical men have gained while working in veins, still, enough has undoubtedly been given to establish the fact of its great solvent qualities.

AN IGNORED INDUSTRY.—"Mining, by virtue of its results, is one of the very foremost industries in California, ranking alongside of agriculture, and as such is entitled to due consideration. The writers who ignore this fact fail to meet the wants of their supporters, and by no means advance the interests of the commonwealth. If necessary, let them devote a little less space to dwelling upon the mineral resources of Nevada, Arizona, Mexico, Colorado, and other outside sections, and tell something about that of which the inhabitants of California at present know so little—the mines of their own State." Thus speaks the Nevada City Daily Transcript. It complains that the operations of the gold bunters are hardly noticed, except at the expense of a dozen words or so. We think that more attention might be devoted to the mining interest of this State by our local exchanges. There is hardly a newspaper in the States and Territories above mentioned that does not contain a great amount of local mining news. The facts are kept before the public intentionally. But we cannot say the same of all of the newspapers of this State. There is such a paucity of mining news that San Francisco papers are compelled to be brief. When the gold hunters' operations become as important to local journals as the war in Africa, for instance, or politics, there will be more mining news in the city papers.

DURING the progress of the Grant party through Iowa, the train at one point made 45 miles in 40 minutes.

Rolling Stones.

Habit has much to do with the roving disposition of our hardy prospectors, and if in the great hereafter, those who have benefited mankind to their own disadvantage, are to receive any reward, the gold hunters of our great West deserve one in the shape of a special corner, where they can sit, and smoke, and spin yarns about the rich finds they unearthed and the millionaires they have made. It is undoubtedly the fate of all men to succeed best in that for which they have a particular calling, and failure most always attends attempts to vary it. It is the luck of the prospector to succeed admirably in making grand discoveries, but it is his fate to run away to some new field, leaving the old one to those whose calling is to stick. It is said that hundreds of prospectors, with pick and shovel, are now making their way to the new mines of the Sierra Mojada, in Mexico, where they will encounter new hardships and expose themselves to every danger. "This," says the Grass Valley Union, "seems like an unwise thing to do, and yet just such men as the old California prospectors are the ones who made our State and the neighboring State of Nevada what they are to-day. We owe the discovery of most of our mines and also the great Comstock lode to them. They very seldom reap the reward of their findings, but they are still ready to pack up their few tools and go in search of new wealth, only to be enjoyed by some one else. It does not matter, as a general thing, how well they are doing in the place where they

New Zealand Gold Fields.

Late advices per Thames Advertiser mention an accident to the Big pump, caused by the wearing away of the packing. The pump is 70 feet under water, and the only way to get at it was to send a diver down the shaft, but after four days' trial gave up the job. Upon the operations of this pump depend the workings of several mines, which will have to be given up for the present, and until a proposed "lift" pump is put down to clear the water as far as the 400 level, which if successful will leave the plunger chest dry and enable the pump to be repaired.

The new mining road along the base of Una hill and up the Papa gully, is nearly finished. It will enable many claims to be worked which are now at a standstill, there being no means of bringing ore to the crushing mills on the flat.

In the Golden Calf some good gold has been come on, a leader four inches thick having been intersected on the Moanatairi side of the slide, in a portion of the property hardly ever worked before. The quartz shows strong colors of the precious metal, and a small parcel of the stone has been broken out. The Alburnia seems to make the best showing, however, the reef (ledge) on the 70 level west being about three feet thick and heavily charged with mineral. Mr. Radford expects, in driving this level, to come under the run of gold now being worked at the Whau level stopes, and he has been getting good gold lately. Seventy level, east: The lode is about three feet through, and shows a little gold. The leader lately cut in this drive is now being driven on, and shows gold, some rich specimens coming to hand occasionally. Stopes, 70 level: These stopes continue to give a good supply of crushing dirt, and show strong colors of gold. Whau level: Stopes are giving good payable crushing stuff, with a few pounds of specimens and picked stone. Battery: 213 tons of quartz have been crushed during the month for the return of 363 ozs. 6 dwts. of gold. The prospects of the mine appear much improved, and the manager is of opinion that when the 160 feet of Dixon's low level has been extended under where he has been driving in the 70 level, that rich stone will be discovered.

A RAILROAD TO BODIE.—From appearance we expect to be able in a short time to congratulate Bodie upon the possession of a railroad. The Virginia Enterprise of recent date says: Mr. D. O. Mille, who is at present in New York, has negotiated for the material necessary to extend the Virginia and Truckee railroad from the Mound House, via Mason valley, toward Bodie 60 miles, and the order has been, or will be in a day or two, given for the ties. So soon as the material can be landed here, active work on the construction will be commenced. We have often referred to the advantages which this railroad extension will work. It will awaken active life in five or six mining districts which are now well nigh dead; it will enable heavy machinery and building material to be carried to Aurora and Bodie at a reasonable cost, and it will also place 200,000 acres of first-class land in Mason valley convenient to market. This alone will furnish 1,000 families with comfortable homes on the best continuous body of land in this State. It will place Belleville, Candelaria, Marietta, New Boston, Columbus, Benton, and Indian districts within one day's drive of the railroad; it will bring Lake district, Belmont and Alida valley nearer Virginia City than Aurora now is. It ought, by the time it is finished, to give active work to 4,000 more miners than are now employed, and the farming population of the State ought to be increased by at least 800 families. With its completion the taxable property of Esmeralda and Lyon counties ought to double.

A LOVELY MINING REGION.—Judging from a letter to the Galveston News the Mojada mines of Mexico are pleasanter to stay away from than to settle in. The writer intimates that if all the reports of richness are true, yes, even if the whole range of mountains were composed of pure silver, it would be no inducement to go to a place where the nearest saloon or bakery is 125 miles distant. Besides all who go there must expect to leave their wives widows. When an American arrives at the Sierra Mojadas the Indians and Mexicans administer upon his estate without the preliminary inquest held in other countries upon the corpse of a rash adventurer. Then, too, if death is escaped, and the American has begun to dig out the ore, he will have to pay the Government 25 cents on the dollar to start on. The coinage, portage, and finally stealage, will bring the cost on the dollar up to about 115 cents. The returned Texan appears to be prejudiced against this new mining region, and argues that the United States will not protect American citizens who are endeavoring to civilize Mexico by squatting upon her silver mines.

MINISTER KASSON will soon go to Bucharest to formally recognize the independence of Roumania and establish diplomatic relations between that country and the United States.

CAPTAIN CAREY, who was with the Prince Imperial at the time of his death, is to retire from his regiment and enter the church.

Flaming Gorge, Green River.

A Government party several years ago explored the canyons of the Colorado of the West. They first proceeded down the Green river, which enters the Uinta range by a flaring, brilliant-red gorge, visible from the north at a distance of 20 miles. The great mass of mountain ridge through which the gorge is cut is composed of bright vermilion rocks; but they are surmounted by broad bands of mottled buff and gray, which come down with a gentle curve to the water's edge on the nearer slope of the mountain. This is the head of the first canyon of a series made by the river through this range. The cliffs are about 1,200 feet high. Major Powell named it Flaming Gorge. Our engraving illustrates the picturesqueness of the scenery in that neighborhood.

THE bale of cotton donated for the benefit of the orphans of Gen. Hood was sold and resold several times at Houston, realizing \$1,000. Then it was shipped to Waco.

THE latest news from New Mexico is to the effect that the command of Major Morrow is pursuing Victoria and his warriors into Mexico.

AN old mining town, hitherto unknown to the whites, has been discovered in Arizona.

Scientific and Practical Books
 on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
 MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick-silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

UNITED STATES
Mineral Land Laws, Revised Statutes
AND INSTRUCTIONS AND FORMS
UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Surveys; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to often give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., 202 Sansome St., S. F.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

ALLEN GOVERNOR.

This Governor is now being generally adopted throughout the United States and Europe. It is without doubt the

Most Perfect Engine Regulator in Use, And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised, it can be returned at our expense.

In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure. Send for full descriptive circular.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, bolting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is hoisted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SCIENTIFIC PRESS ENGRAVING CO.,

No. 202 Sansome St., S. F.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No hedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

Mines and Works of Almaden.

Translated from "Annales des Mines"
BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

CONTINUED FROM PAGE 293.

up and getting larger as we drive north on the vein. We have drifted north on this ore commencing at No. 3, raise, a distance of 70 ft in length, and I believe now it will prove to be part of the Transylvania ore body.

THE RISO MINE.—This mine has been bonded to some San Francisco parties, who intend to work and develop it in a systematic manner. Parties who have examined the mine believe it to be a valuable property. Certainly the ore is not high grade, but then there is so much of it, and it can be so easily extracted that it is sure to pay any company well that takes hold of it. At a depth of 30 ft the ledge is 9 ft wide, and it keeps increasing in width as greater depth is reached. The striking of more water than he could handle was what compelled Mr. Riso to quit work in it. Some men are now at work in the mine putting things in shape for an early start.

EUREKA DISTRICT.

CALIFORNIA.—Sentinel. For some days past ore assaying from \$50 to \$70 per ton has been taken from the California mine, which adjoins the Consoli on the south. Its proprietors, Joe Mendes and Alex. McKensie, have just refused \$20,000 for the mine, and say they have half that amount in ore now in sight.

MOUNT ROSE DISTRICT.

BULLION.—A writer in this *Paradise Reporter*, of November 1st, speaking of this mine, says: I never saw before such vast quantities of rich ore as was there to be seen. The ledge is six to eight ft wide, and rich in the precious metals from bangle wall to footwall, not a barren spot to be seen. The ledge runs as Chote canyon on the north, and Singhas on the south. Course of ledge so far as I was able to judge by the course of the ridge and general trend of the country rock is south southeast by north northwest, the country rock being granite syenite, with small gouge of porphyry lining to ledge, which is four ft wide, one foot of ore assaying from \$236.62 to \$2,200 per ton. Character of minerals, copper, silver, glance, black mica, with small amounts of ruby. I was told that native silver also had been detected in fine particles in some of the ore.

MARY WILDER.—The same writer says: Two men, a few days ago, found this new quartz ledge, six miles west of Paradise village, in the Paradise range. It is situated on a ridge making down from this granite mountain, and the head of what is known as Chote canyon on the north, and Singhas on the south. Course of ledge so far as I was able to judge by the course of the ridge and general trend of the country rock is south southeast by north northwest, the country rock being granite syenite, with small gouge of porphyry lining to ledge, which is four ft wide, one foot of ore assaying from \$236.62 to \$2,200 per ton. Character of minerals, copper, silver, glance, black mica, with small amounts of ruby. I was told that native silver also had been detected in fine particles in some of the ore.

NORTHUMBERLAND DISTRICT.

BLUE EAGLE.—Belmont *Courier*: From Mr. Stonebarger we learn that the work of development is progressing satisfactorily in the Blue Bell and Blue Eagle mines, and that ore is being extracted at a rapid rate. There is a large quantity of good milling ore in sight in both mines, and hauling to the mill was begun last week. The mill will start up about the 1st of November, and Mr. Stonebarger feels confident of making a long and profitable run.

PISCHE DISTRICT.

IRFMS.—Record. Nov. 1: Last Monday the Newark mine was again started up, this time under the auspices of Ryan & Co., who have leased it for a term of months for the purpose of obtaining screenings for leaching. The American Flag mine has been leased for two years by responsible parties, who will soon start to work on it. The American Flag has a large deposit of smelting ore. Some miners are working on the Amador tunnel property. They recently extracted 30 tons of screenings, which were leached, yielding \$43 per ton, leaving \$3 per ton in the tailings that were run off.

RAYMOND & ELY.—Supt. Mill, in his last report, dated October 31st, says: The stopes on the 1100 level look very well and promising; the winze is now about 5 ft and good ore is being mined and prospects are looking very flattering. We are running drifts east and west of the winze; the west drift looks very well and the ore is three ft wide. Have now 300 tons of ore at the mill, which will start up again on or about the 3d prox.

ARIZONA.

GLOBE DISTRICT.—Silver Belt. The bustling works of the McCormick M. Co. have arrived on the ground and are to be speedily put into motion, when a large force will be put on the mine. Work will be commenced on the Hannibal mine at McMillen after the 1st prox. under the superintendence of Chas. McMillen. Ed. Cummings, Secretary of the company, will return to take charge of the books. The strike on the Antler mine at McMillen promises to be a big one. The stratum of native silver, several inches in width, resembles the one that made the Stone-wall Jackson, of which the Antler is a second extension south, so famous and from which hundreds of thousands of dollars were taken. Buck & Hayes' mine on Salt river prospects well. An average of 12 assays gave a result of over 500 oz. per ton in silver. Frequent assays for gold from this mine have given astonishing results, going high into the thousands. A working test is to be made soon in the Isabella mill.

TOMBSTONE.—The *Weekly Nugget*, of October 30th, says: John Haley, the owner of the Anchor mine, has made an open cut into the ledge about 10 ft deep, and from the footwall the bottom and sides are in ore, from which assays have been made going all the way from \$156 to \$2,000. It is a beautiful carbonate, and the ledge is easily traceable 8 ft in width along the claim for a long distance and keeping its width as the shaft descends. The formation is limestone, with a bangle wall of porphyry, capped in lime.

SILVER KING MINE.—The *Arizona Silver Belt*, of Globe, Arizona, in its issue of November 1st, speaking of the late strike in this mine, says a 60-foot crosscut at the depth of 250 ft, in the new shaft, reveals a body of high-grade ore of almost incalculable extent. The crosscut is in solid ore from the beginning, and is yet the opposite wall has not been reached. Shaft No. 1, 400 ft east of the working or new shaft, has attained a depth of 300 ft, where the vein shows an uninterrupted body of ore, 25 ft from wall to wall. The vein is unbroken from top to bottom of this shaft.

COLORADO.

SAN JUAN.—The *Prospector*, published at San Juan, Del Norte county, says: Carbonates have been discovered about 6 miles north of town. A reporter visited the new camp and found the entire country staked and work being done on several locations. While this is, in reality, a new discovery so far as silver and carbonates are concerned, it is not new in the matter of gold quartz, having been worked to some extent in the summer of 1876, but at that time nothing but gold was thought of, and, like Leadville, carbonates were unknown to the average prospector. Attention was first attracted to this new discovery by Wm. Bingham, who forwarded some of the ore to Morgan E. Draper, at Lake City, for analysis. The returns from four assays showed that the rock carried about 7 or 8 oz. of silver to the ton and a small percentage of gold. Then began the real excitement, and since that time numerous locations have been made in the vicinity.

GEORGETOWN MINE.—Georgetown *Courier*, Oct. 30: The product of this mine is said to be larger than any other mine in the State with the exception of two or three carbonate mines at Leadville. The numerous workings running in every direction expose rich veins of quartz and ore from 3 to 20 inches in thickness, and assaying all the way up to \$800 oz. per ton, some of the ore veins being solid, that on the \$30 level, which Dalton & Co. are working, carrying large quantities of gray copper. The *Tropic* mine, near the whole distance, the vein ranging from 6 to 13 inches in thickness. In the main workings the 100 level is being pushed both east and west, and in both directions it continues in good ore. The ore mills about 125 ozs. in silver, 1/2 oz. in gold, and from 2% to 7% copper.

IDAHO.

SNAKE RIVER.—The *Enterprise* says: We are informed that the Secretary of the Idaho Snake River G. M. Co. has

arrived at Eagle Rock, the headquarters of the company, and that work will be commenced on the mines at once. The company owns the Black Canyon mines, comprising 80 acres of mining lands, and said by many to be the richest claims on Snake river. The contracts for the ditching have been signed, and the mining machinery is being made East and in Ogden. The company has a process for working the mines and saving the gold, superior to any that has yet been placed on the river. We have reliable information that one man has been quietly at work on the river with perfected machinery of his own, getting out \$400 per day.

YANKEE FORK.—The *St. Helena Independent* says: The Montana mine, in the Yankee Fork country, was found in a real glacier. Sixty feet of the surface croppings had been broken off and carried some 30 or 40 ft down the mountain. The owners, knowing the glacier never moves up hill, followed upward through the ice and frozen ground until they reached the point where the ledge was broken off, finding it as large and quite as rich as below. The company's ore house, dump, etc., are all on the glacier, but its movements are not perceptible, if indeed it is moving at all.

MONTANA.

BONANZA CREEK.—Helen *Independent*: This prospect is now attracting much attention, both on account of its unusual richness and its peculiar formation. For a distance of about 66 ft in the direction of what was supposed to be the trend of the ledge, and about the same distance transversely, search has been made for and found the largest deposit of ore yet found in this region. Jasper, malachite, agate and iron are mixed and mingled in a confused mass, and through all is found good pay of the "yellow dust." At a depth of 26 ft there is no apparent change in the character of the deposit. It is estimated by competent observers that there are 800 tons of ore now on the dump, and, in a miner's phrase, there is three times that amount in sight. We understand that the present mill is to be enlarged to 20 stamps, and complete pumps and hoisting works put up by Eastern parties.

CATACACT MINE.—Butte *Miner*, Oct. 23: Col. Black's "Mantis" lode is not so fabulously rich as at first supposed. There is a 4-inch vein of rich rock which assays very high, and this vein has been traced for about 300 ft. The entire vein averages 3 ft, but the value of the ore throughout has not been ascertained. Riley owns the Independence lode, on which he has sunk a 30-ft shaft. This mine looks well, and is probably as promising as any lode in the camp. There are great numbers of lodes in the vicinity, some of them assaying quite high in silver.

RICH STRIKE IN BELCHER.—The *Belcher M. Co.* for some time have been engaged in running a crosscut tunnel through the Rainbow vein to strike the Belcher lode, a continuation of the Alice, owned by Wm. Bros. At a point about 150 ft from the tunnel mouth they cut through the hanging wall and exposed about 2 ft. of ore assaying from 106 to 372 ozs. in silver, and carrying from \$40 to \$50 in gold to the ton. Pushing the tunnel ahead and across the vein they passed through 16 ft of mixed ore and gangue, showing silver and gold by assay, but not enough of either metal to warrant the saving of it for pay. Beyond this another streak of ore was cut 15 inches in thickness, showing better than the former one, but no assays have as yet been made of this new find. The tunnel is being driven steadily ahead by contract, and is still in vein matter. It is the intention of the company to drive the tunnel completely through or across their ground, which will give a total length of about 600 ft, and it is known that at least two other veins will be cut by it. This lead already cut has all the characteristics of the vein shown in the Alice workings, and it is evidently the same ledge.

NEW MEXICO.

GRANT COUNTY.—The *Herald*, published at Silver City, says: We understand that Thomas Lyon's mine, situated about half way between the Belmont and Moccasin, is in operation in splendid style. The specimens brought in assay from \$300 to \$800 in silver, and the ore is increasing in quantity as well as improving in quality as work progresses.

OREGON.

MAMMOTH MINE.—Bedrock *Democrat*, Oct. 29: Another link in the added to the mine and resources of southern Oregon—the Mammoth quartz ledge, discovered in 1867, on the mountain, eight miles from Sumpter, but for the want of experience in mining and the lack of energy, it remained undeveloped until last spring, when a company of miners purchased the property and opened up the mine, taking out several hundred tons of very rich ore. Becoming satisfied of their purchase, a five-stamp steam mill was bought and erected. It being completed last week, the stamps were put in motion, and after a few days' run the sum of \$400 was realized, and forwarded to this city. Several specimens of rich ore from this mine are on exhibition at the bank of J. W. Virtue, Esq.

NEW PLACER DIGGINGS.—An exchange says: J. G. Henrica, of Portland, has found gold placer diggings on Wildcat creek, on the north fork of the John Deis river. He and his partner found gold in paying quantities, and the "old fever" has already struck a number of people in that locality.

Arizona's Railroad Prospects.

Considerable that is flattering to Arizona was uttered by Judge Underhill of the S. P. R. R. in an interview with Major Hall, published lately in the *Washington Republican*. Judge Underhill says, however, he does not think it equal to Nevada or Colorado in either its mining wealth or agricultural resources. As far as mining developments have been made, it would seem the richer portions of the Territory are adjacent to the line of the Southern Pacific railroad, as built and proposed; also that section lying between the railroad and Prescott, to which latter point it is designed to construct a branch road at an early day. It has an excellent climate, however, and is a fine stock-grazing country. Many of the lands designated as "desert" will bear the best of crops with water on them, and many of them can be irrigated by the rivers, and a large portion probably by the sinking of artesian wells.

The Judge's private opinion is that a railroad will not very soon be built with Guaymas or any port on the Gulf of California as terminus. Upon this subject he says: I have heard it suggested that the China and East India business would seek a port on the Gulf of California, and thence take its way East by rail, but any one that understands the winds, currents and distances of the Pacific will know that can never be done, as all sailors from those countries come down on the trade winds, and would pass near San Francisco, which is about 1,600 miles from Guaymas, and the last half of the distance in light, variable winds which sailors so dread—and steamers certainly would never think of going there when they could stop at the port of San Pedro, on the Southern Pacific railroad, nearly 1,000 miles less steaming than to go to Guaymas, and then be very little, if any, nearer the junction of the two roads.

Recent Decisions Relating to Patents, Etc.

U. S. Circuit Court, Southern District of New York.

Webster Loom Company vs. Higgins et al.

Decided January 14th, 1879:

1. Patents are to be construed in the light of what was before known to persons skilled in the art to which they relate in order to give effect to the true meaning of what is there described.

2. The description in a patent must be so full and plain that a fairly competent workman in the art could take it, and, exercising the then existing knowledge of the trade, follow it out, and by it, without addition or invention, construct an operative machine containing the parts mentioned in combination.

3. If it requires experiment and invention to make and use the matter described, the patent is invalid.

4. The several parts of a machine or device may combine in producing a result and yet not constitute a patentable combination, but only a mere aggregation.

5. In the absence of other evidence, the date of the patent is to be taken as the date of the invention, and the burden of proof is upon the defendant to show, beyond any fair doubt, prior knowledge and use. When such evidence has been produced, the burden is shifted upon the plaintiff to show still earlier invention.

The following decisions are by the Commissioner of Patents.

Anvils—Ex-parte Duch.

Decided June 18th, 1879.

The combination of a drill, adjustable standard, and vise with an anvil, as such, is not a legitimate mechanical combination, for the anvil, as such, can make no contribution to any distinct operation of the entire machine. But the combination of a drill, adjustable standard and vise, by means of a hasp to which the standard and vise are attached is a legitimate combination embracing no supernumerary elements, and, if novel, is patentable.

Time-Locks—Ex-parte Kook & Hall.

Decided July 8th, 1879.

When different forms referable to one genus are such that the substitution of one for another involves invention, the differences are patentable, and the several forms constitute different species of the genus, all subject to one generic patent, but each legally patentable in a distinct and specific patent. When, however, the substitution of one for the other involves no invention, but only mechanical skill, the differences are not patentable and the forms do not constitute several species of the genus, but are all modifications of the same species.

NEW MINING MAP.—We acknowledge with pleasure the receipt of a handsome map of the Lake mining district of Mono county, California, as surveyed and published by Wm. S. Lillien, U. S. Deputy Surveyor, and approved by the representatives of the mines of the district as correct. The map is tastefully arranged, with the claims colored and clearly distinct. The district appears on the map lying east of the headwaters of the south fork of Owens river, and snugly within a bend of the same, which widens into seven quite large lakes, which form an excellent water supply. Mammoth and Pine City also appear on the map as centers of their respective claims. We fancy the map as also the location of the district.

SOUTHERN CALIFORNIA.—This is the title of a pamphlet just published by C. H. Phillips, of San Luis Obispo, and designed for circulation among immigrants and colonists seeking homes on this coast, with a view to aid in the settlement of southern California, and particularly San Luis Obispo county and vicinity. Arrangements have been made for the free distribution of several thousand copies at Omaha and other Eastern points. The expense of this edition of 10,000 copies, together with the cost of the 20,000 maps, has been more than the small subscription in aid of the work will meet, consequently, a few thousand extra copies are for sale, and will be mailed to any address in the United States, postage paid, at 25 cents each.

Thanksgiving.

Proclamation.

At no recurrence of the season, which the devout habits of religious people have made the occasion for giving thanks to Almighty God, and humbly invoking his continued favor, has the material prosperity enjoyed by our whole country been more conspicuous, more manifold or more universal. During the past year also unbroken peace with all foreign nations, general prevalence of domestic tranquility, the supremacy and security of the great institutions of civil and religious freedom have gladdened the hearts of our people, and confirmed their attachment to their Government, which the wisdom and courage of our ancestors so fitly framed, and the wisdom and courage of their descendants have so firmly maintained, to be the habitation of liberty and justice to successive generations.

Now, therefore, I, Rutherford B. Hayes, President of the United States, do appoint Thursday, the 27th day of November, instant, as a day of national thanksgiving and prayer; and I earnestly recommend that, withdrawing themselves from secular cares and labors, the people of the United States do meet together on that day in their respective places of worship, there to give thanks and praise to Almighty God for his mercies, and devoutly to beseech their continuance.

In witness whereof, I have set my hand and caused the Great Seal of the United States to be affixed.

RUTHERFORD B. HAYES.

New View of the Debris Question.

A new idea has lately been suggested by an exchange in regard to the debris troubles, which if it does not compensate for any damage alleged to have been done in the past by the accumulation of waste material upon fertile soil, may at least throw a ray of light upon the chaos of opinions foisted upon the public as remedies against the complained of evil. It is an open question whether the courts can settle the disputes between the hydraulic miners and farmers to the full satisfaction of both parties, and it must be evident that in any event mining will not be stopped, nor will our agricultural lands be destroyed. Even if hydraulic mining should be interdicted, it would not afford a remedy for the damage already said to be inflicted upon agricultural lands. Our exchange puts it in the following light:

The rivers are already full of debris, and every creek, brook and gulch that feeds them. Should mining all cease now, it would require half a century—probably half a dozen centuries—to clean them out and restore their beds to their condition in 1852.

What, then, shall be done? What can be done? We cannot dig the debris out. That would be more than a herculean undertaking. It is thurs to stay at least until this child born yesterday shall reach old age. It is idle to expect any substantial assistance either from the State or the nation. There is nothing in our system of government that is paternal. It allows the widest range for people to take care of themselves, but it never bothers itself to take care of them. If a state or a county gets into trouble, it kindly lets it get out the best way it can. If it will not vote subsidy to construct dykes for the protection of Louisiana or Mississippi, we may be sure it will not assist us to dam back the waters of the Yuba and American for the protection of the private land contiguous. If it should, then Louisiana and Mississippi would demand the like paternal favor. Neither will the State Legislature lend a hand. If it should attempt to, the taxpayers not directly interested would pierce the sky with howls of indignation against it, and they are greatly in the majority.

This question recurs, then, What shall, what can be done? The owners of this land and town property threatened will have to do it, whatever it may be. Nobody helped brave old Sacramento to raise her dykes and her grade. Nobody will help the farmers and land owners directly interested in this emergency. They will have to help themselves as the Hollanders did. And if they do it wisely and well they will be able, like the Hollanders, to turn a seeming calamity into a great blessing. If they will combine and dyke in their lands against the annual winter and spring overflows, as the Netherlands have been protected against the Scheldt and Meuse, with floodgates for irrigation, they will soon discover in the abundance of their harvests that it is better, far better, to have the rivers running nearly on a level with their farms than in their original deep channels. In this way some hundreds of thousands of acres of land hitherto believed to be of no account, may be converted into fertile fields, adding millions of bushels of grain to the yearly production of the State, and that with positive certainty. The season of high water is the season when irrigation or the flooding of the grain crop is needed, that is to say, from January to May. No irrigation is required for grain after the middle of May, when the rivers begin to recede rapidly. If Bear river were properly dyked and provided with facilities for flooding the land during the winter and spring months its valley would become a paradise of fertility instead of this desert it now is.

Of course the question of money damages for the injury already claimed to be done is not contemplated here, upon the principle, we imagine, that the raising of the river beds is a compensation therefor, inasmuch as it affords better irrigation facilities. We give this view of the debris question for what it is worth, and without expressing an opinion as to its merits.

EXPLORERS', MINERS' AND METALLURGISTS' COMPANION.—J. S. Phillips, M. E., has just completed the publication of the first volume of the third edition of the above work, in library and pocket size. The work is as complete as any work of the kind can be, and is in another shape that it may be conveniently carried in the pocket by the prospector. The first volume, now ready, is complete in itself as an explorer's and assayer's companion. The volume is full of useful and important information in every branch of the mining business, and that it is favorably regarded appears from the fact that a third edition was called for. This has been issued, and contains much new matter. Mr. Phillips is his own publisher, as he has been from the start, and is deserving of commendation for his energy in successfully evolving the problem of author and publisher.

In New York, Government bonds are quoted at 102 1/2 for 4s of 1907; 102 1/2 for 5s of 1881; 106 1/2 for 4 1/2s; sterling, \$4.81 1/2 @ \$4.83 1/2; silver bars, 116; silver coin, 1/2 @ 1/4 discount.

News in Brief.

ELIZATIONS in eight States last Tuesday.
EX-EMPERE EUGENIE has returned to Chiselhurst.

POTATOES retail at four cents per pound at Enreka.

BISMARCK is suffering from neuralgia and sleeplessness.

CARLOTTA, ex-Empress of Mexico, is recovering her reason.

SPAIN is to dispatch additional reinforcements to Cuba immediately.

A SEVERE gale was experienced on the Atlantic coast last Monday.

JACOB ABBOTT, the author, died at Farmington, Me., aged 76 years.

GENERAL SALOMON has been proclaimed President of the Republic of Hayti.

THURSDAY, the 27th, is named by the President as a day of thanksgiving.

AN epidemic typhoid fever and measles prevails at Cape Clear, Ireland.

A RAILROAD is to be built between Santa Barbara and Newhall, 80 miles.

THE Pennsylvania Railroad Company has declared a semi-annual dividend of 2 1/2%.

It is rumored in London that Russia is preparing to declare war against England.

HEAVY rains have fallen in the Argentine Republic, dispelling all fears of a drought.

THE death of John Baldwin Buckstone, the famous English comedian, is announced.

SIXTY-SEVEN persons have perished from hush fires in the province of Minas-Geraes, Brazil.

THE French Government will not allow Methodist ministers to preach to the soldiers.

THE Spanish Council of Ministers has decided to abolish the state of siege in the Basque provinces.

THE storm in Nova Scotia last week damaged Prince Edward's Island to the extent of \$60,000.

SILVER in London, 53 1/4d; consols, 97 13-16; 5% United States bonds, 105 1/4; 4s, 105 1/4; 4 1/2s, 104 1/2.

ALL Spanish officers are to contribute one day's pay to the relief of the sufferers by floods in Murcia.

THE report of the suspension of the Russian expedition against the Tekke Turcomans is confirmed.

THE death of Charles Gruncion, the noted theologian and biographer, is announced from London.

LACK of money in the San Francisco school fund compels teachers to discount their pay warrants.

THE total value of the pieces coined at the United States Mint during October is given at \$6,198,254.

THE thermometer at Memphis, Saturday, fell to 37°, sweeping away all lingering germs of yellow fever.

SEVERAL persons have been drowned and 26 houses destroyed by floods in the province of Hnascar, Spain.

At Liverpool, wheat is quoted at 10s 9d to 11s 9d for average California white, and 11s 7d to 12s for club.

THE difficulty regarding the shipment of the Egyptian obelisk to New York has been amicably arranged.

OFFICIAL returns show that 3,065 French Communists have been amnestied, about 1,000 remaining exiled.

THE Prussian budget shows the deficit for the next fiscal year to be \$11,901,810, which will be covered by a loan.

A DISEASE called the "black tongue" has caused the death of several persons at London, Ont., and vicinity.

FURTHER gales and floods have occurred in Spain, doing great damage to property and drowning 60 persons.

THE Liberals were mostly triumphant in the English municipal elections, wherever political considerations were involved.

IN San Francisco, half dollars are quoted at par; trade dollars, 95 buying, 96 selling; Mexican dollars, 96 buying, 96 selling.

THERE is a well authenticated report on the Comstock that the north header of the Sutro tunnel is encountering streaks of ore.

THE wells used by a German colony in Besarabia were recently poisoned, making 100 persons ill and causing the death of five.

THE annual Christian co-operation of the State of Oregon, is to begin at the Christian church in Independence, Polk county, on Tuesday.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Hillside, Nov. 1st, \$5,000; Northern Belle, Oct. 29th, \$5,933.10; Con. Virginia, Oct. 29th, \$103,760.78; Belle Isle, Nov. 3d, \$25,000; Ophir, Oct. 26th, \$75,837.36; Christy, Nov. 4th, \$7,762; Leonard, Nov. 3d, \$3,500; Alexander, Oct. 31st, \$6,663.40; Northern Belle, Nov. 1st, \$7,685.96; Hillside, Nov. 4th, \$4,500; Gila, Nov. 5th, \$6,847; Alexander, Nov. 3d, \$5,255.75.

A NEW PAPER.—We welcome the Monitor Argus, a new paper published by P. W. Parker, at Monitor, Alpine county, California. It is quite young, and we must say it, small for its age, but, for all that, contains much more mining news than some of its older and bigger contemporaries.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

(From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.)

FOR THE WEEK ENDING OCTOBER 23TH, 1879.

221,011.—STEAM GENERATOR.—D. Abell, Carson, Nev.
220,965.—HINER FOR DOOR DOORS.—J. Decombe, S. F.
220,978.—AMALGAMATOR.—A. F. Ladd, S. F.
220,923.—CAR TRUCK.—E. J. Marsters, Stockton, Cal.
221,045.—FIRE ESCAPE.—P. Gallagher, Eureka, Nev.
221,051.—WINDMILL.—R. Lorocho, Loyalton, Cal.
220,940.—VENTILATING MINES.—W. B. Norman and R. H. Leonard, S. F.
2,104.—Title, "STRASSMAN'S BLOOD RENOVATOR. The best alternative and depurative ever discovered."—Label—Max Strassman, S. F.
2,105.—Title, "STRASSMAN'S RADICAL RESTORATIVE."—Label—Max Strassman, S. F.
2,106.—Title, "STRASSMAN'S REPARATIVE BALSAM."—Label—Max Strassman, S. F.
NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

IMPROVEMENT IN APPARATUS FOR MAKING AND LAYING CONTINUOUS CONCRETE PIPE.—Ezra M. Hamilton and Charles N. Earl, Los Angeles, Cal. Patent No. 220,757, dated Oct. 21st, 1879. This invention relates to an improved method and apparatus for the manufacture of concrete or cement pipe, and it consists of a cylinder or case, which is laid horizontally in the trench prepared for the pipe, said cylinder being provided with a piston or plunger, which is operated by hand, and which forms the pipe from the mortar or cement, which is fed to the cylinder from a feed tube or hopper on top. A flexible core is attached to the end of the piston, which forms the orifice through the pipe, the pipe being thus made in a continuous piece, without joints of any kind, so that any leakage is avoided.

WRENCH.—Andrew Jackson, 143 Fremont street, San Francisco. No. 220,076, dated Sept. 30th, 1879. This device relates to an improved universal wrench, and it consists of a novel combination, with other devices, of a stationary and a movable jaw, the moving ends of which are separated or closed in a line diagonal to the handle by means of a screw which actuates a movable nut. The movable jaw is hinged to this nut so as to open or close at will, and is kept closed by a spring. The invention also consists in certain details of construction, whereby any form of nut or pipe may be seized and turned. The tool is simple, easily and rapidly fitted to any nut, bolt or pipe, and has few parts to become broken or get out of order.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Oruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How to STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Iron and Machine Works.

THOS. PENDERGAST.

HENRY S. SMITH.

ÆTNA IRON WORKS,

MANUFACTURERS OF

IRON CASTINGS

and MACHINERY

OF ALL KINDS.

Fremont Street, bet. Howard and Folsom,

SAN FRANCISCO.

UNION IRON WORKS,

SACRAMENTO, CAL.

ROOT, NEILSON & CO.,

MANUFACTURERS OF

STEAM ENGINES, BOILERS AND ALL

Kinds of Machinery for Mining Purposes.

Flouring Mills', Saw Mills' and Quartz Mills' Machinery constructed, fitted up and repaired.

Front Street, between N and O Streets,
SACRAMENTO, CAL.

PHELPS

MANUFACTURING COMPANY,

Manufacturers of all kinds of

Wharf and Bridge Bolts, Railroad Trestle Work, Car Frames and Bolts, Machine Bolts, Set Screws and Tap Bolts, Lag or Coach Screws.

ALL STYLES OF FANCY HEAD BOLTS.
HOT AND COLD PRESSED HEXAGONAL AND SQUARE NUTS, WASHERS, BOLT ENDS, TURNBUCKLES, ETC., ETC.

13, 15 and 17 Drumm St., near California,

SAN FRANCISCO, CAL.

Golden State & Miners Iron Works,

Manufacture Iron Castings and Machinery of all Kinds at Greatly Reduced Rates.

STEVENSON'S PATENT

Mold-Board AMALGAMATORS,

Golden State Pressure Blowers.

First St., between Howard & Folsom, S. F.

Main Street Iron Works,

WM. DEACON, PROPRIETOR.

Noe. 131, 133 & 135 Main St., San Francisco.

Stationary and Marine Engines,

Shafting, Pulleys, and General Machine Work. Jobbing and repairing done promptly and at Lowest Rates. Screw Propellers, Propeller and Steamboat Engines.

SAW MILLS and SAW MILL MACHINERY.

California Brass Foundry,

No. 125 First Street, Opposite Minna

SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc, and Babbitt Metal Castings, Brass Ship Work of all kinds, Spikes, sheathing Nails, Rudder Braces, Hinges, Ship and Steamboat Bolts and Gongs of superior tone. All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and Connections of all sizes and patterns, furnished with dispatch. PRICES MODERATE. J. H. WOOD. V. KINGWELL.

WM. H. BIRCH.

JOHN ARGALL.

California Machine Works, BIRCH, ARGALL & CO.,

119 Beale Street, San Francisco.

General Mechanical Engineers and Machinists. Steam Engines, Flour, Quartz and Mining Machinery. Sole manufacturers of Brodie's Patent Rock Crushers and Steel-Faced Tappits. Agents and Manufacturers of F. A. Youse's Patent Steam Packing Rings for Steam Pistons. The best ever invented; can be applied to any Engine Piston and give entire satisfaction to those using. Steam, Hydraulic and Sidewalk Elevators. Repairing promptly attended to.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Captains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Books for Miners and Millmen

KUSTEL'S ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated. 142 pages. 1870. A valuable and carefully written work. Postpaid, \$2.50. Published and sold by Dewey & Co., S. F.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphures, arseniures, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 672 pages and 83 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Postpaid, \$10.50. Sold by Dewey & Co., S. F.

ARON'S TESTING AND WORKING SILVER ORES.—Illustrated. 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Postpaid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Postpaid, \$1.00. Sold by Dewey & Co., S. F.

SAVE YOUR GOLD !

Highly Important to Miners and Quartz Mill Men !

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

Trall Hygienic, Medical and Surgical Sanitarium.

No. 8 Ellis Street, San Francisco, Cal.

Treatment by a Purely Scientific and Rational Method Without Drugs of any Kind.

THE TREATMENT DEPARTMENT EMBRACES ALL APPROVED REMEDIAL AGENTS, AS OXYOEN INHALATIONS, VACUUM TREATMENT, THERMO-ELECTRIC, TURCO-AMERICAN, ELECTRO-MAGNETIC, GALVANO-CHEMICAL, STEAM, VAPOR, WARM AIR, AND ALL FORMS OF WATER BATHS;

Swedish Movements, The Health Lift, Spirometer or Lung Strengtheners, Steam Atomizers, all Electric, Galvanic and Surgical Appliances, Sun Baths, and Solar Ray Surgery, new and perfect Truss for the Radical Cure of Hernia, lately discovered Chemical Compound for the speedy, safe, painless and permanent removal of Cancers, Scientific and successful method for the Cure of Piles, etc., etc.

Aims to keep Abreast with, if not in Advance of the Progressive Age.

It has been the mission of this System to mold public sentiment and this Institution will hope to be no disgrace to the immortal name it has assumed. The time has come when Physicians of this School can afford financially to keep a conscience; in fact it is disastrous financially as well as morally to compromise the truth one-day, hence patients can rest assured that they will be treated by the Physicians after the most approved and scientific methods, out of pure and enlightened selfishness, recognizing the truth and beauty of this great principle: "The Universe is so ordered and arranged that the real and permanent good of every creature is best subserved in promoting the real and permanent good of every other being."

THE BOARDING DEPARTMENT.

The table will be supplied with the best the excelsior market of the world affords, embracing fruits, grains, vegetables, meats, fish, fowl, eggs, cream, etc. Regular and transient boarders will be accommodated as well as patients. Business and professional men and women who are tired of restaurant fare, may appreciate eating to live a more healthful and enjoyable life. Pure food means pure blood. Pure blood means good health.

"The vegetarian school has demonstrated beyond the possibility of a doubt that farinaceous dishes, sweet milk and fruit, are sufficient to maintain a hard working man in perfect health. Such a diet might certainly be substituted by sedentary people for their greasy steaks and ragouts." - Popular Science Monthly, December, 1878.

The Rooms are pleasant, warm, well ventilated and sunny; convenient to treatment rooms, so as to afford the best advantage of nursing and professional attendance.

GENERAL PRACTICE.

Fevers, and in fact all cases may be treated at home successfully. Parturition, confinement cases are taken in the Institution or attended at home in any part of the city or country. Preparatory treatment in these cases is most important.

Testimonials of extraordinary cases and cures can be seen on application. The most desperate cases, and especially those that have been given up as incurable by the old methods, are invited. Puerperal and typhoid fever and diphtheria cases, after all other methods have failed, may be said to be a specialty. Send for the TRALL HEALTH JOURNAL.

H. C. PATRIDGE, Prop'r.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from fouling or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

A New Mining Law.

A new mining law has been drafted by Congressman Belford, of Colorado, which it is intended to introduce at the next session of Congress. It has been published in the Colorado papers, in order that miners and others interested may have opportunity to criticize it and suggest amendments. The proposed law is as follows:

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled.

"That hereafter any persons desirous of prospecting and exploring the public domain of the United States for the discovery of deposits of gold and silver-bearing ore, which do not outcrop or appear on the surface, may locate a mining claim 1,500 feet in length and 600 feet in width, which location shall be made by marking the boundaries of the same on the surface of the ground by at

least six substantial stakes, one at each corner of the claim and one at the center of each side line.

"After the making of said location, the party making the same shall have 90 days within which to expose and define the mineral deposit, which may be done either by the sinking of a discovery shaft, or by an open cut, cross-cut or tunnel. If within said period of 90 days, he shall fail to expose said mineral deposit, his location shall be void, and the claims so located shall be open to re-location in the same manner as if no location of the same had ever been made.

"No person discovering a mineral deposit under this act shall have the right to follow it beyond the point where it is intersected by the exterior lines of the claim; nor shall any person under this act be allowed to locate a second claim in the same mining district, until he has perfected his title to the first located claim by an exposure of the mineral deposit therein, in the manner above set forth and by recording the same as required by law.

"Provided, this act shall not apply to mining claims on veins or lodes of quartz found between well-defined walls of rock in place."

It is quite probable that proposed changes in the mining laws will be suggested to the next Congress. That changes should be made admits of no argument, but the importance of changes for the better cannot be over-estimated. It is less difficult to make the law incomprehensible than it is to clear away its inaccuracies. If the

proposed law of Judge Belford's is intended to be a new law, it does not repeal any of the legislation under which mining is now conducted, except by inconsistency, which is one of the worst features in any law, since it compels a law suit to decide upon whether the construction is compatible or not with any preceding law. The bill belongs to that feature known as special legislation, and leaves the door open to unsurmountable difficulties. It provides stakes as the evidence of location, to be proven by oral testimony, leaving the reording of the claim out altogether, thus increasing the troubles of the miners.

Veins and lodes are especially excepted from the operation of the act by the proviso at the end, and hence refers exclusively to placer claims, and affords no relief.

The proposed bill fails to give any special protection to the miner, since it leaves the loca-

liver the miner from geological technicalities; not a system which, for instance, will, like Judge Belford's proposed law, put the carbonate deposits out of the legal category of veins, and leave the deposits of other districts in their present status. The bill itself does not do this, although intended, but increases the difficulties of the situation by endeavoring to make it applicable to deposits elsewhere of an entirely different nature.

Leffel & Co's New Works.

We present herewith an engraving representing the new works of James Leffel & Co., Springfield, Ohio. The manufacturers of the well-known Leffel improved double turbine water-wheel, have found that their facilities were unequal to the growing demands of their

their popularity. The various parts of the wheel have been greatly improved. Among the most noticeable modifications and additions made (some of which are patented), are the improved link for operating the gates; the process for lining the iron plates with brass or any anti-corrosive metal; the combination of the toothed segment with the gate-arm in such a manner that the segment can be removed when the teeth become worn and a new one supplied; the spherical iron penstock; the use of steel as guides for most of the sizes, instead of iron; and the improved method of casting solidly in one piece both wheels, by which means the edge of the diaphragm can be made much thinner and yet stronger, assisting to separate more perfectly the due proportion of water to each wheel. Half the buckets being made of good boiler iron, they are not liable to break or tear out any of them. Any part of the wheel, accident-

NEW MANUFACTORY OF THE LEFFEL TURBINE WATER WHEEL.

least six substantial stakes, one at each corner of the claim and one at the center of each side line.

"After the making of said location, the party making the same shall have 90 days within which to expose and define the mineral deposit, which may be done either by the sinking of a discovery shaft, or by an open cut, cross-cut or tunnel. If within said period of 90 days, he shall fail to expose said mineral deposit, his location shall be void, and the claims so located shall be open to re-location in the same manner as if no location of the same had ever been made.

"No person discovering a mineral deposit under this act shall have the right to follow it beyond the point where it is intersected by the exterior lines of the claim; nor shall any person under this act be allowed to locate a second claim in the same mining district, until he has perfected his title to the first located claim by an exposure of the mineral deposit therein, in the manner above set forth and by recording the same as required by law.

"Provided, this act shall not apply to mining claims on veins or lodes of quartz found between well-defined walls of rock in place."

It is quite probable that proposed changes in the mining laws will be suggested to the next Congress. That changes should be made admits of no argument, but the importance of changes for the better cannot be over-estimated. It is less difficult to make the law incomprehensible than it is to clear away its inaccuracies. If the

tion open to exploration until ore deposits are discovered. The period of 90 days amounts to nothing and is worse than nothing in the present law, because every miner has 90 days in any event, while here he must find an ore deposit within that time or give up the claim to others. It provides not for the indigent miner, who may have reason to believe he has an ore deposit, but has not the present means to find it within the required 90 days, while the heavier purse can stand quietly by and take possession at the end of the required time.

The nature of the ore deposits of Colorado and Utah are different than those in California, and hence the law now in force is difficult of application. The changes to be made, however, will, it is hoped, remove the difficulties experienced in those localities without, at the same time, doing injustice to the deposits of this State and of Nevada. It would seem, from the very nature of the differences, that special legislation would be necessary, but that would be worse than the present law. We need above all things some uniform system which will de-

business and have, therefore, constructed the new buildings shown, fitted throughout with the most improved and expensive machinery made especially for the firm.

The buildings cover several acres of ground. The main building is occupied principally by the machine shop, and the L contains the foundry. Besides these, there are large pattern shops, pattern rooms, blacksmith shops, core rooms, and offices, as well as projected hoiler shops, etc., which are detached from the main building. These works form the most extensive and thoroughly equipped establishment in the world for the manufacture of water wheels.

The heavy nature of much of the work done by the firm, renders it desirable that most of the shops be on the ground floor; a portion of the main building, pattern shops, etc., are, however, two stories high. All the departments have ample capacity, are conveniently arranged and well lighted.

There are over 8,000 of the Leffel wheels at work in different places and under all sorts of circumstances, a fact which indicates clearly

ally broken, can at once be duplicated. Efficient as the wheel has been, by the aid of new and special machinery the working parts will be characterized by even better workmanship than heretofore.

SIGN OF PROSPERITY.—The *Arizona Citizen* notes as an indication of prosperity the gradual increase of litigation stimulated by the rich mining developments in the various mining districts, and quotes a favorite remark of A. T. Stewart, who whenever he desired to know of the financial importance of a place, always inquired the number of lawyers in that place, for said he, "where there is an abundance of lawyers there is always plenty of business." We judge, says the *Expositor*, by this standard Tucson to be the most prosperous town on the planet.

It is said Bismarck is not only suffering from his old neuralgic complaints, but symptoms of a constitutional malady have appeared, causing some apprehension.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Alpine County Mining.

EDITORS PRESS:—In looking through the columns of your valuable paper we never see an item regarding the mining progress of Alpine county, and still our county could furnish you with very interesting material regarding the very successful treatment of our most rebellious ores. Our county, like other mining districts, had its time of excitement. Capital came in, mines were opened and large mills were built, but, to the great loss of the investors, it was soon found that our ore was too rebellious to be worked successfully. One camp after the other, with nice mineral deposits in sight, died of consumption. Amalgamation, the Freiberg process, leaching, and several other processes had been tried, but without success, till finally the whole county had almost been deserted. One company, the "Advance," however, showed more endurance than the balance, and kept up working and experimenting, though without success, till July, 1878, when they engaged Mr. Ottokar Hofmann, a Freiberg man, and one of the best metallurgists of the coast, who, without any previous experiment, put up his vats and pipes, and inside of two weeks commenced to ship bullion. Alpine county had not been used to ship bullion, and Mr. Hofmann's success created quite a sensation, and gave hope and confidence to the old settlers. The problem of working our rebellious ore had been solved at last. Mr. Hofmann, however, left us soon, as other business called him back to San Francisco, and the Advance company did not survive his departure long, as previous fruitless experiments brought it in heavy debt, which caused the property to be attached by the creditors.

On the strength of Mr. Hofmann's success the Colorado No. 2 G. & S. M. company formed itself last winter and brought the Tarschbich property for about \$20,000. This property is the best in the county, and comprises a valuable mine and a 20-stamp mill in first-class condition. This property belonged to Mr. Hunter, and was lying idle for many years, as the ore could not be worked. It was an elephant to its owner, who was glad to sell it at the above named paltry sum.

The company engaged Mr. Hofmann, who came up last spring. As soon as he arrived, new life commenced at Monitor. Everybody looked in a bright future. They knew if there was a man to make a success of the new enterprise it was him; and they had not been mistaken. With the small sum of 10 cents assessment on 40,000 shares, as working capital, he started in, tore out the pans, settlers, etc., put up four Frue's concentrators, leaching vats, furnaces, etc., and in a very short time shipped bullion. Who knows the rebellious nature of our ore, containing about equal per cent. in value of gold and silver, and who is familiar with the many previous experiments and failures, has to give great credit to Mr. Hofmann, who, by his ingenious process and thorough knowledge, had such a startling success.

I communicate these facts to you as they may be of great value to many of your readers who are in the same situation as we were during so many years.

In concluding allow me to express my thanks to Mr. Hofmann, who was of such great benefit to the county. In doing so, I am sure to express the sentiment of the people of Alpine county.

Monitor, Alpine Co.

El Dorado County Mines.

EDITORS PRESS:—The Crystal mine at Frenchtown is a recent and promising re-location by Messrs. Morrison & Phelps, of Shingle Springs. It is a little remarkable that some of the best quartz mines of El Dorado county are old claims under new names, or re-locations of mines once partially opened and worked and finally abandoned as unprofitable. Failures took place, in some instances, from mismanagement, extravagance, want of necessary skill, experience, and gold-saving appliances; in others, from high prices ruling at the time for labor, machinery and incidentals, to say nothing of the lack of the necessary capital to prosecute the work to a successful termination.

It was from such or similar cause that the mine now known as the Crystal was laid, like so many others, on the shelf. In this day, when \$5 rock under similar conditions is made to pay, it is difficult to realize a failure with quartz represented to average \$15 per ton from a vein six feet wide, and a good mill near the mouth of the tunnel. The tailings are said to have been rich, a sufficient amount of gold having been cleaned up from the mortar blocks under the battery to pay the purchase price of the mill when removed. The present owners are very sanguine that they have struck a good thing. They have stripped the surface of the ledge for 200 feet in length and 25 feet in width, and find much of it prospecting well in free gold. They claim a chimney of ore about 300

feet in length by 60 feet in width, from which thousands of tons can be thrown down in readiness for the mill by the simple process of quarrying it out, the greater portion of which, they hope, will give good returns. The ledge has a species of green slate on the western wall, and syenite on the eastern, and is traceable a considerable distance north and south. They are understood to be making arrangements for the removal of an eight-stamp mill to the mine, to which other stamps can be added after thoroughly testing the ore.

The Ailanthus Silkworm.

EDITORS PRESS:—I have seen in some of the papers a small item alluding to a new kind of silkworm from China, tested by M. Ledoux, and regarded as superior to those with which experiments have formerly been made in this country. Can you give us fuller information about it?—L. C. W., Mission San Jose, Cal.

This insect to which reference is made is the "ailanthus silkworm" (*Atacus [Samia] cynthia*), called *ailanthus* because of its feeding naturally on the tree of that name (*ailanthus*, or *ailantus*—"tree of heaven.") This silkworm cannot be called new, for it has been known more than a century to entomologists and has been advocated for culture for many years. It is grown in Europe, and Prof. Riley says it has become so common in some parts of the Eastern States as to be a nuisance. What there is new in the item to which our correspondent alludes is the work of M. Ledoux, and that lies in a discovery or process for securing the silk from the cocoon. At the last meeting of the American Association for the Advancement of Science, held in July last, a paper was read upon the ailanthus silkworm by Prof. C. V. Riley, U. S. Entomologist, which is a full review of the insect and the possibilities with it, and would be read with interest by all agriculturists. Such space as we have at command will only enable us to glance at the comparison which Prof. Riley makes between the culture of the ailanthus worm and the mulberry worm, and this, we believe, is what our correspondent most desires to know.

In brief, the culture of the ailanthus worm is an out-door affair; that of the mulberry worm, is an indoor industry. Prof. Riley says of the former species: "There is little trouble in raising the worms. It is best to raise them in the open air, care being taken to protect them from attacks of birds and predaceous insects, such as ants, ground beetles, etc. The trees, however, may be trimmed that an awning of some light material could be stretched over them during the feeding season. A few cocoons, well chosen for size and quality, might be left on the trees for breeding purposes, and the moths as they issue would soon pair naturally and the females deposit their eggs upon the branches of the trees. Two broods can easily be produced each year, and the time of hatching of the eggs, of the issuing of the moth, and that required for the development of the worm, depends so much on the temperature, that the broods can be produced at the seasons most convenient and favorable. When this control is denied, the eggs and the cocoons must be properly managed. The cocoons intended for breeding purposes may be suspended in chaplets, so that the moths may issue more readily and have a good opportunity to hang their damp wings as they expand. They may then be coupled and placed in wicker boxes or any other well ventilated vessel, from which the eggs, when laid, can be easily removed. The eggs when about to hatch may be fastened to the trees in various ways, so that the young worms, from the first moment of their lives, will find the leaves convenient. They may be pasted on to thin wood, paper or linen, and pinned in small quantities to the leaf stalk; or portioned into lots of fifty, or hundred, and suspended in small muslin bags pinned near a leaf. The young worms are gregarious and generally remain on the side of the leaves; and as they do not consume much at this period, and are more liable to the attacks of their enemies, it may be found profitable to rear them during the first stage indoors upon cut branches or young trees in pots.

The silk of the ailanthus worm is no doubt very valuable, but to what extent, depends on our ability to manufacture it successfully. It has several disadvantages, but native ingenuity may devise some means to overcome them or turn them to account. The value of any silk-worm depends on our ability to unwind its cocoon. I cannot see from the accounts that have so far reached that M. Ledoux's invention accomplishes anything more than that of former inventors, and, whatever impetus it may give to *ailanti*-culture, we may rest perfectly satisfied that such culture will never become general, and that the *ailanthus* silkworm will never replace that of the mulberry.

The prime reason why the mulberry silkworm must ever be the silk producer of commerce, aside from the superior quality and quantity of its silk, is that it is a domesticated insect and that the worm can be fed in large quantities in partial confinement and under control; further, that, while enduring this artificial life, it shows no disposition to escape from the shallow trays upon which it is fed. All the other worms suffer more or less when brought together in large numbers, or when confined or sheltered, and in this fact more than in any difficulty in using the silk, lies the secret of the failure to substitute any of them for *mori*. The hardness and adaptability of *Cynthia* to different climates cannot offset this objection; for it remains essentially a wild worm, and it will require many centuries of selecting and artificial rearing ere it can be domesticated to the same extent that is

the *Sericaria mori*. There never can be any dependence placed on the production of silk from worms growing wild on their food-plants, as in such state their exposure to birds and other enemies will always render the cocoon harvest uncertain, and it is far more expensive and troublesome to protect both the wild worms and the trees on which they grow, than it is to rear the mulberry worm by the ordinary methods employed.

Imported Game Birds.

EDITORS PRESS:—Can you tell us what has become of the Eastern quail and Australian pheasants, which were introduced some time ago in the hope that they would enrich our game resources, etc.—S., San Francisco.

We sought information on these points from Hon. B. B. Redding, of the California Fish Commission, as it was under the auspices of the commission that the praiseworthy attempts at acclimatization were made. The Eastern quail were set free in two localities. In the Montezuma hills in Contra Costa county they have done well, and have become quite numerous, because they were preserved by the farmers, who would not allow them to be shot. Those liberated near Woodland, in Yolo county, were all killed and marketed within three months.

The English pheasants were set free two years ago upon Goat island, San Francisco bay. The first year they were preserved by Gen. McDowell's order prohibiting shooting on the island, and the pheasants were frequently seen, but have not been observed since then. Their loss is accounted for by two surmises. One is that the birds may have flown to the main land. Another is that they have all been captured by the great number of cats which live in a wild state upon the island. These cats are the offspring of numerous garrison felines, which were left upon the island when the soldiers were withdrawn, and which have lapsed into a wild-cat style of life. Another lot of pheasants were set free two months ago upon land owned by the Spring Valley Water Co., near one of their reservoirs. As no hunting is allowed upon this land the birds have escaped the buntsman. They have been carefully preserved and fed, and under these favorable conditions have prospered thus far. They have remained near the place where they were liberated and are occasionally seen. It is probable that they will nest next year and firmly establish themselves.

The wild turkey of the northwest, which were placed upon Santa Cruz island by Judge Caton, have found plenty of food, and are reported to have shown signs of increase and permanent residence.

Mr. Redding suggests the great advantage of introducing the migratory quail of Europe, of which we gave a description and illustration in our issue of May 17th, 1879. This bird has been introduced by the bundreds in Vermont and Massachusetts, the stock being brought from Messina. The species is very destructive of grasshoppers and other field insects, and thus could do excellent service in our valleys, which are occasionally afflicted with such pests. As the bird is migratory in its habits, it might find congenial southern residence in Arizona and Mexico. For a northern home it could select its habitation according to its tastes, as our State from mountains to coast could nowhere suitably like of the bird. This quail is most rapid in its multiplication, and being a good game bird would please the hunter as well as the farmer, whose crops it might help to guard from destroying insects.

Mr. Redding mentions the advisability of the appointment of a commission to secure and introduce valuable foreign birds to this State, and the suggestion is one we can heartily approve. Many competent, and public-spirited men could be found who would do the service without pecuniary compensation, merely for the satisfaction of enriching the State in the direction of feathered treasures. Their work would be analogous to that of the fish commission, and the gentlemen composing that body (although Mr. Redding did not mention it), are doing a public service, which is already showing its value by evidence which is as tangible as a man's breakfast. We trust the creation of an acclimatization commission to secure the introduction of valuable insectivorous birds will be one of the benefits conferred upon our great producing interest by the coming Legislature.

Tuolumne County.

EDITORS PRESS:—This is truly the land of excitement and the home of plenty, from an "orphan squash" to a "barley" flower, from Bodie to Tioga. And now we have a mineral bonanza, bordering the great plains, on Widow Olsen's land. The find is some four miles from La Grange, on the Tuolumne, twenty miles from Sonora and eight miles from my place, in a southerly direction. The vein is 12 feet wide, red-burned quartz, almost of a porphyry nature, and unlike any other vein ever found in this State. The main find has been sold by the prospectors, and handed to capitalist by Mrs. Olsen for some \$20,000. Croppings and locations have been made miles apart from the first find, on Dennis Phalen's property. Capitalists are excited, workmen are on the ground, houses are being erected, and before the outside world learns of the rich strike, a small town will spring up where sheep used to roam. Truly this is a wonder land.

JOHN TAYLOR.
Mt. Pleasant, Tuolumne Co., Cal.

Resources of Inyo County.

The *Inyo Independent*, in its issue of October 18th, in speaking of the gold belts of Inyo, says that the "water courses debouching into Blind Spring valley are rich in float gold ore." While we acknowledge that there has been one or two dry washes wherein float quartz has been found, we cannot agree with the *Independent* as to its richness. There has never been any found in that section that would warrant the expenditure of much time or money, and the writer hereof has spent considerable time in prospecting in that part of the country. While in the White Mountain range, after coming south from and leaving Montgomery canyon, no gold is found until the slate belt is reached near Piute district, and the silver-bearing quartz between Piute and Montgomery districts is so nominal in value and so base in character that it will not pay the expenses of working. Another great drawback is the inaccessibility of the canyons and the abruptness of the western slope of the range. There can be no doubt but what there exists some extensive ledges near the heads of some of these water courses; and we have been told by prospectors that there is an immense ledge of gold and silver-bearing quartz on the extreme summit of the White mountains, commencing at a point nearly opposite Whisky flats and running southerly, assaying from \$12 to \$20 in gold and silver, that can be traced a long distance, and which has never been thoroughly prospected, and may be the main lode of the mountains. Further south on the range, and a few miles south of the head of Silver canyon, Messrs. Russel & Givens have done a great amount of work, and found some ore which assays up in the hundreds, and there were several tunnels run and considerable prospecting done in Silver and other canyons during the excitement in the days of old Owensville. Since then little or nothing has been done by any one who can lay claim to the name of a thorough prospector. Further south, as the *Independent* truly says, there has been rich discoveries of gold-bearing quartz made. And then comes the almost inexhaustible base metal deposits of the Cerro Gordo mountains, where immense quantities of rich ore have been reduced. And then the Darwin mines and those of Lookout, Panamint and Wild Rose districts, which as yet have not proved a success, although these ledges have been very rich on the surface they have with one or two exceptions either become barren or else the ore was found to be of too low grade to be worked with profit. This same base metal range can be traced into the Aramogosa range on the eastern side of Death valley, some good ledges having been found in the low range of red hills directly east of Wild Rose. The ore in the New Aramogosa district (which was known as the old Franklin district) carries about equal quantities of gold and silver, with a large percentage of lead.

Many deposits of lead ores of various grades have been found on this range, some rich and some assaying nothing in precious metals, until Resting Springs is reached, where the silver-bearing rock is much richer but found in smaller quantities. Crossing back to the westward we find a few good small deposits of gold-bearing quartz in the vicinity of Snow's canyon; and still further westward there could undoubtedly be found, by careful and proper prospecting, some good gold fields in the old Coso district in what is known as the Slate range. Taken all in all, Inyo county presents one of the most fertile fields for men of pluck and energy to prospect in of any portion of the country. And not only is it a good field for the miner, but here the farmer will find tens of thousands of acres of rich agricultural land that can be homesteaded, and on which, by running ditches, plenty of water can be obtained for irrigation. The one thing needed now to make this one of the most prosperous farming and mining portions of California, is cheap transportation. One great step toward this splendid result is already about to be accomplished, mainly through the efforts of our neighbors across the Sierras, in the construction of the Mammoth City and Fresno Flats wagon road. By means of this opening a new impetus will be given to traffic through this region; and in the near future, when men of capital see the immense advantages of the project, why may we not hope for a narrow-gauge railroad to connect the C. P. R. R. with S. P. R. R. at or near Mobave, thus opening up a country almost unknown, but of unbounded wealth and fertility.

SUBTERRANEAN FOSSIL FOREST.—In the neighborhood of Rotenburg, on the Fulda, Germany, the geologist, Dr. Moesta, has discovered a subterranean oak forest at a depth of eight feet under the ground. The number of well preserved trunks is enormous. The wood is as black as Irish bog oak, in consequence of the influence of water for centuries, but it is hard and sound, and forms an excellent material for wood carving and mosaic. The size of the trunks is astonishing. One of them, about 57 feet in length and 5 feet in breadth, has been preserved for exhibition in the Royal Museum at Berlin. The forest evidently belongs to a very remote period in the formation of our globe.

The following is an analysis of a piece of modern English calico: Cotton, 53; china clay, 26; starch, 12; fatty matter, 2.5; chloride of magnesium, 2; chloride of zinc, 1.5; chloride of calcium, 0.5; moisture, 2.5; 100.0.

MECHANICAL PROGRESS.

Blasting by Compressed Air.

Extensive experiments are now being made at the Pemberton colliery, near Liverpool, in the Reuss system of blasting with compressed air. The plan consists in boring a hole in the coal, inserting a cast-iron cartridge 16 inches long and 3 inches in diameter, and exploding it by compressing air into it. The cartridge is $\frac{1}{2}$ inch thick, and is connected to the air pumps by weldless steel pipes $\frac{1}{2}$ inch outside diameter, and a bare $\frac{1}{8}$ inch bore. The explosion takes place when a pressure of about 8,500 pounds per square inch is reached. The air pumps are mounted on a small trolley which can accommodate its gauge from a minimum of 20 inches upward, the total height of the machine being 33 inches, the width 4 feet 3 inches, and the weight 8 cwt. There are six pumps worked by three cranks on one shaft, and although the enormous pressure required is quickly gained, the pumps are perfectly independent, and the stage process is not used. They are driven by crank handles worked by two collars and geared three to one on the pumps, which latter made 54 to 60 strokes per minute. The rams are $\frac{3}{4}$ -inch in diameter by 10-inch stroke, and work in the barrels without any packing, which is certainly a most remarkable feat considering the pressure attained. There are no suction valves, the admission of the air taking place through holes in the sides of each barrel, which are uncovered when the plunger is at the top of its stroke. The delivery valves are of lead, and are placed close to the bottoms of the pump barrels, which are all screwed into one block of gun metal, from which the delivery pipes start. The bases of the pumps work in water to keep them cool. A great deal of the success of the operation depends on the truth with which the hole is bored in the coal for the reception of the cast-iron cartridge, and to accomplish this Mr. Reuss uses a small universal hand-drilling machine, the supporting bar for which is made fast to the face of the coal by expanding wedges at its foot let into a hole jumped in the coal for this purpose. The cutter for making the cartridge hole has a diamond-pointed center, and cuts on both sides, and clears itself well at the edges. It makes holes about 40 inches deep, into which the cartridges are placed, and well tamped with sagger clay and the borings from the holes just made. The pipes connecting the pumps and the cartridge are joined together with couplings, having soft copper washers placed between the ends of the pipes to insure tight joints, and the last length of pipe is screwed into the end of the cartridge, which is increased in thickness for this purpose.

CURIOSITY FOR PIANO PLAYERS.—At a late musical festival in Worcester, Mass., a spinet was exhibited bearing the inscription: "Jacobus Kirchmann, fecit Londini, 1755." The year 1710 or 1711 witnessed the invention of the pianoforte, but its introduction to general use was very gradual. Haydn, Mozart, Beethoven and musicians of their day undoubtedly used the spinet or the larger instrument of the same family, the harpsichord. This instrument above mentioned, is in shape somewhat like a grand pianoforte, in dimensions $7\frac{1}{2}$ feet on the straight side, 3 feet at the keyboard end with a depth of case of 11 $\frac{1}{2}$ inches. It rests upon a standard, which is detachable and easily folded together. It has no pedals, but knobs at the sides of the keyboard allow mechanism to give or take of extra volume of tone. The "action," so-called, consists of a "jack" at the end of the lever, a wooden upright, with projecting pieces of leather to twang the string as it passes upward, and a little cloth damper to stop the vibration when the jack is lowered. The strings were of copper, brass and steel, the lowest of about the same dimensions as the highest in modern pianofortes. The "eyes" at the further end of the strings were as regularly and evenly made as those of the present day, while the tuning ends were merely wound about the pins, without passing through holes in them. Five octaves of keys give tones from the fourth line below the base staff to the fourth space above the treble.

THE BRACHYTELESCOPE.—In conjunction with Forster, Fritsch, the well-known Viennese instrument maker, has brought out a reflecting telescope, which has now been long enough before the public to secure a certain amount of approbation. The rather equivocal name, brachytelescope, has been given to this instrument on account of the shortness of its tube. The telescope is so light that it can be lifted about with its stand from place to place by a single pair of hands, a telescope of ordinary construction being, for the same power, of far greater length and weight. The rays of light sent from the object fall first upon the large concave reflector inclined at any determined angle to the optical axis of the instrument, and converge thence to fall without obstruction on the small convex mirror placed at the top part of the apparatus. The image is formed behind the large reflector, when it is seen magnified through the lens in the eyepiece. Both mirrors are made of silvered glass, and have parabolic surfaces. The instrument does a great deal of work at a low cost. With a four-inch reflector the double stars, gamma Virginis, beta orionis, the Polar star, the pair of double stars, eta Lyrae, etc., are distinctly separated.

New Testing Machine.

A testing machine constructed at the works of the Paris, Lyons and Mediterranean Railway Company at Paris (M. E. Marie, engineer-in-chief), is the most important machine of its kind. It is designed simply for tension, and arranged for a maximum pull of 100,000 kilogrammes, or nearly 100 tons. The whole construction of this machine is exceedingly simple.

The test piece is connected at its lower end to a rod carried through from a hydraulic ram, working in a vertical cylinder placed below the bedplate. The weight of this rod and the ram, etc., is balanced by a counterweight suspended in a pit under the cylinder, but for the sake of avoiding shocks the connection between the chains and the counterweight is not direct, but through a system of springs conveniently placed within the counterweight.

The upper end of the test piece is carried by a link from knife-edges on the principal lever, from which the pull is transmitted to a second lever above the machine and thence down to the steelyard, which is placed conveniently for reading at the side of the machine. The maximum obtainable leverage is 600 to 1. The weight of the system of levers is counterbalanced by a special lever on the top of the machine. The weight on the steelyard is movable by means of a screw, and the load can be read either on a scale on the steelyard itself or on the peripheries of a system of graduated disks, arranged with a differential motion, placed at the outer end of it. This allows the load to be measured to (approximately) 0.005 of a kilogramme.

The hydraulic pressure is obtained either by a three-ram pump, from an accumulator, or by one of Thomasset's compressors. The extensions are measured by a kathetometer specially arranged for the purpose which allows of estimation to the one-thousandth part of a millimeter. The machine is substantial and well designed, and its workmanship is very good throughout. The test piece itself is well exposed to view, as are the different parts, which also—except that they are a considerable height from the ground—are very accessible. We may add that a drawing of a machine on the same system intended to test chains has been exhibited by the same company. The chain is placed horizontally, of course, and the machine can take in a length of 30 meters, and exert a maximum effort of 100,000 kilos.—*Engineering.*

THE RAILROAD UP MT. VESUVIUS.—The latest reports from Naples represent the railway destined to carry tourists to the top of Vesuvius as progressing fast towards completion, and the walls of the station which forms its terminus, are already rising above the ground. The line is to be laid along the western slope of the mountain, and will be rather less than 1,000 yards in length. The station itself, which stands at the bottom of the volcanic cone, is 2,500 feet above the level of the sea, and the line rises rapidly from thence to the verge of the crater, at an incline which averages 56 feet in the 100, but reaches at its steepest part as much as 63 in 100. The construction of the railway has been a matter for serious debate, and it is only after long consideration that the projectors determined upon the system planned by the engineer, Olivieri. According to the principle adopted in this plan, the whole of the inclined plane, from top to bottom, is covered with a thick platform of wood resting upon the lava and other crumbling soil, which would of itself be much too unsteady to form a proper bed for the sleepers. Above the cinders and detritus, of which the mountain side is composed, the platform will be like a gigantic raft, and upon it the rails will be laid with ease and regularity. The wheels of the carriages are to be so firmly attached to the rails that they can never jump or slip off, and the trains are to be drawn up by means of two steel cables worked by a steam engine stationed at the bottom of the volcano. They will also be provided with a brake so powerful that even in the unlikely case of a breakage of both cables they can be brought to a standstill very quickly, even in an incline of 50 in 100. The only other difficulty which faced the projectors of the new railway was that of water supply, for it was calculated that the expense of bringing from Resina enough water to supply the engine, would run away with more than all the profits that could reasonably be expected. In order to avoid this alternative, two large reservoirs are being constructed, which are expected, even under the peculiar circumstances of the position, never to run dry.—*London Globe.*

A NEW KIND OF SCALES.—A pair of scales based on the physical law that the weight of a floating body is equal to the weight of the volume of liquid displaced, has been patented by Weckermann, an engineer at Kalk, near Cologne. Two hollow cylinders with closed bottoms, of exactly equal weight and dimensions, serve as floaters, and are introduced into two somewhat larger cylinders, communicating at the lower ends, and partially filled with the supporting liquid. On top of the floaters are placed the weight pans, provided on their inner rim with a pair of indicators precisely opposite each other when the balance is at rest. A weight placed on one platform depresses the cylinder, equilibrium being of course restored by an equal weight on the other side. Reducing the diameters of the floaters increases the sensitiveness of the apparatus.

SCIENTIFIC PROGRESS.

Preservation of Iron from Rust.

Dr. Treumann, of the Hanover Technical High School, says: Iron surfaces exposed to the action of water for any length of time, whether constantly or intermittently, should not be surfaced with boiled oil. It is a commonly admitted fact that water will soften linseed oil varnish even when it has been more or less completely converted to resin. Every painter knows how crushed remnants of paint in the pot can be softened by filling the pot up with water, and letting it stay there some time. Exposed continuously to the action of water, oil colors applied to iron surfaces blister in the course of a few days. Then the paint gets loose, and in the course of a few months is completely destroyed. If the paint has been let down with oil of turpentine or benzine, so as to be laid on thin, the coating endures for some time under water, but is totally destroyed by a few months' continuous immersion. Emulsion is the besetting evil of paints made from solutions of resins in the products of the distillation of tar, in oil of turpentine, in wood or coal tar, in oils, benzine, and the like. They are subject to the same evaporative action and lowering of temperature which is followed by such damage in the case of oil varnish, and therefore have no superiority to it. The chemical composition of some of these substances, too, is such as to be a direct occasion of rust. The products of distillation of wood tar contain acids, and these should be removed completely before use. Such complete removal, however, is very rarely effected. The products of distillation of coal tar occasionally contain salts of ammonia, and are thus a source of injury to iron.

Where water has to be resisted spirit varnish or Dammar lac varnish should be employed instead of oil varnish. Spirit varnish, consisting of alcoholic solutions of resins, occasions cooling by the rapid evaporation of its vehicle, but is less subject to damage by water than the above mentioned substances. The spirit varnish, to be quite safe in using it, should neither contain fat, fatty oils, or tar oils; and, therefore, the matters added to make it flow better should be as sparingly employed as possible. Supposing the spirit varnish to be used in what we may term a normal condition, its power of resisting water will depend on its content of resin. Resins are precipitated from their resinous solutions with water, since they are not soluble in alcohol of a certain degree of dilution. The same thing happens when alcoholic solutions of resins remain in presence of water, and it happens the more rapidly the larger the amount of resin present, and the larger the dilution of the alcohol employed for its solution. The sensitiveness, therefore, of alcoholic solutions of resin to the damp deposited upon the painted surface in consequence of evaporation increases with the proportion of resin, and falls with the proportion of spirit. The conclusion to be drawn from this is, to bring the proportion of resin as low as possible, regard being had to the hardness requisite for the vehicle which has to carry the mineral color.

ECONOMY OF NATURE.—The deep-sea dredging carried on by the American Fish Commission, under the charge of Prof. A. E. Verrill, of Yale, between Saybrook and the Bay of Fundy, has discovered more than 50 kinds of fish previously unknown, at least in American waters, and many of which are quite palatable. The habits and histories of the different fish and animals are obtained, together with the localities where each species most abounds, what they feed upon, when they breed, and under what circumstances, and their migration. The fishes are opened and the contents of the stomach examined to see what they eat. This is a very important branch of the investigation, and the most that is known in that line has been obtained through the commission's researches. Before that, not even the fishermen knew what was the food supply of the most common fish. That point known, the reason of the absence or presence in a locality of any particular fish could readily be ascertained. Where herring has been found in large quantities one season, would not know them the next, and the reason would be the absence of their favorite food. Their diet is shrimps. The latter feed on almost invisible crustacea, and these again on microscopic creations. The presence of the latter would bring the crustacea, to be followed by the shrimps, the herrings, and the whales and sharks, in the order named. So it is seen what an important part even the most minute things may play in the economy of nature. The knowledge obtained in this branch of the inquiry, will teach the fishermen not to destroy the food supply of their prospective prey.

MOLECULAR CURRENTS.—Ampere asked if the molecular currents of magnets are entirely created in the magnetic substance during magnetization, or if the magnetizing cause merely determines a circulation of currents pre-existing in the metals in their natural state. He inclined to the latter opinion. The author thinks that there is every reason to admit, with Ampere, that the particular currents pre-exist in the magnetic metals, and that the current of the battery merely determines the circulation and the direction.—*M. Treve, in Comptes Rendus.*

TRIANGULATION OF NEW YORK STATE.—In a recent lecture at Rochester, Prof. James T. Gardner, Director of the State Survey, gave the following explanation of the method of triangulation adopted in making the survey of the State: The first work of triangulation is to select a point on a hill, dig a hole five feet deep, and bury in it an earthen pot over which a granite post four feet high and six inches square is put. Six inches of it is left out of this ground. Within three feet of the monument are two more posts with arrow-heads on them pointing to the center of the monument. By these measures the central point is preserved beyond any chance of obliteration. Peculiar poles are used to be set over the monument, to assist the surveyors in locating the station from another point. On each post is a thin cone, to reflect the sunlight, which may be seen under favorable circumstances 40 miles. Where woods are too thick to be cut down, structures are built to elevate the signal above the trees. The process of measuring angles is most delicate, and in some cases have to be re-measured 300 times, the reason being that a line of light does not move in a straight line twice. To overcome this difficulty, an instrument called the heliotrope is used. By means of this instrument a ray of light can be flashed 50 or 60 miles. The instrument throws the light from a small mirror, and it appears to the spectator like a star. In general, observations must be taken in the early morning and late afternoon, on days when there is little refraction. Some days there is so much refraction that no observation can be made accurately. The instrument for measuring the angles measures to one-three hundred thousandth of an inch.

THE BLACK MILDEW OF WALLS.—Prof. Paley attributes the blackness of St. Paul's Church, London, mainly to the growth of a lichen, and Prof. Leidy recently stated to the Philadelphia Academy that his attention was called a few years ago to a similar black appearance on the brick walls and granite work of houses in narrow, shaded streets, especially in the vicinity of the Delaware river. Noticing a similar blackness on the bricks above the windows of a brewery, from which there was a constant escape of watery vapor, in a more central portion of the city, he was led to suspect it was of vegetable nature. On examination, the black mildew proved to be an alga, closely allied to what he supposed to be the *Protococcus viridis*, which gives the bright green color to the trunks of trees, fences and walls, mostly on the more shaded and northern side, everywhere in that neighborhood. Prof. Leidy thinks it may be the same plant in a different state, but until proved to be so, he proposes to distinguish it by the name of *Protococcus lugubris*. It consists of minute round or oval cells, isolated or in pairs, or in groups of four, the result of division; or it occurs in short irregular chains of four or more cells up to a dozen, occasionally with a lateral offset of two or more cells. The cells, by transmitted light, seem of a brownish or olive-brownish hue. In mass, the alga appears to the naked eye as an intensely black powder.

PROPAGATION OF CODFISH.—The labors of the United States Fish Commission at Gloucester, Mass., is devoted to the hatching of cod. This is the most difficult of all, for the eggs have to float upon the surface until the hatching is completed. Something over 5,000,000 were successfully propagated last year. The fishermen there were very skeptical at first, and scoffed at the idea of men coming from Washington to teach them, who had been in the business all their lives and knew all about it. And they were very much pleased when the scientific men, battling against many odds, made a failure of the first attempt. Success, however, attended a second effort, and the fishermen were called in to see the result. Even then they could hardly believe it, and said that what was shown them was only a lot of pollywogs, which the commission had procured somewhere to fool them. They were, indeed, like pollywogs at first, but they flourished and soon took upon themselves the appearance of cod. The harbor is now full of the little three-inch-long cod, and last summer the fishermen were delighted to take visitors down to the dock and point out the little wigglers. The commissioners hope that these young cod, when they take to the sea, will, like salmon and shad, return to the place of their propagation to spawn, and the result of the experiment is awaited with much interest.

A PREHISTORIC WELL IN MAINE.—John Upham, of Camden, Me., had occasion to dig a ditch on his farm, sinking it between one and two feet deep. After proceeding some distance he encountered a rock-maze tree, over a foot in diameter, lying between one and two feet below the surface. Following this up he found it separating in two branches, one of which he cut off with an ax, and, removing the branch thus severed, discovered under it a well all stoned up, about three feet deep and about the same diameter. Contained within this enclosure was a hoiling spring of excellent cool water, which has supplied the family since, never becoming dry in summer, nor freezing in winter. The wonder is, when and by whom was this well dug, and how long has the earth which was above it been swimming? It would seem to be too limited an estimate to calculate by a few hundred years, and not too great a stretch of credulity to look back some thousands of years for its origin.

[illegible]

CONTINUED ON PAGE 316.

Experimental Geology.*

It has been objected to geology as a science that its conclusions were frequently based upon insufficient premises, and that it was lacking in actual demonstration. Indeed, a writer of eminence once described geologists as a set of persons who amused themselves by constructing worlds, and then pulling them to pieces again; and it must be confessed that the reckless guesses of an imagination not always scientific, which have at times obtained a temporary notoriety, did in some cases justify the charge. Still it should be remembered, as M. Dauhree points out, that this study of the earth, after having been for a long time hypothetical, did really, towards the end of the last century, enter "une voie positive," where it has taken for its guide the observation of facts.

Exactly a century has elapsed since the first appearance of de Saussure's works on the Alps. Werner and Hutton followed shortly, and the endless dissertations of their respective disciples may perhaps have had something to do with the strictures previously mentioned, especially as they took root in those soils where discussion on subjects more or less transcendental seems to be an indigenous plant. Yet, even in the earliest years of the present century, the importance to this geologist of the synthesis of minerals was recognized, although it was at one time considered that the divergences between certain minerals and the most analogous compounds which the laboratory could furnish was such as to render their actual reproduction impossible. The differences between crystalline quartz and the amorphous silica of the chemist was almost as great as that between the diamond and the soot of our chimneys. To effect such marvels, lapse of time and certain occult actions were deemed necessary, or, as Leihnitz put it in the *Protogaea*, "il faut du temps, du repos, et de l'espace."

In 1805 Hall experimented with a view to control some of Hutton's views, and succeeded in making chalk semi-crystalline under the influence of heat and pressure, whilst Haussman, a few years after, turned to account in the interpretation of geological phenomena the examination of the silicates of the metallurgical furnaces.

The year 1823 marks a discovery of the most importance. Mitscherlich recognized that peridot, pyroxene and other mineral species crystallized in slags, and Berthier, by melting silica with different bases in definite proportions, actually obtained crystalline combinations identical with those of nature, especially pyroxenes. It was the first step made in the direct synthesis of minerals.

The next step was to overcome the difficulty presented by insoluble combinations in the wet way, and Haidinger, being desirous of controlling Von Buch's hypothesis, inaugurated the employment of water under pressure in the formation of dolomites, whilst the numerous minerals accumulated in metalliferous lodes, which observation had shown could not have been conveyed either in a state of volatilization or of fusion, attracted attention with a view to their reproduction in the wet way—no easy task, when it was seen that silica itself in separating from water assumes the condition of opal rather than of quartz. This void in synthetic mineralogy was snatched filled by the employment of appropriate substances, such as arsenic, most widely distributed in existing thermal springs, operating at temperatures above 100° C., and under pressure. In this way he succeeded in the formation of quartz crystals, small, it is true, but possessed of this physical and optical as well as the chemical properties of natural quartz. Since then another triumph of synthesis has been scored by Hantefeuille in the artificial production of orthose and albite.

Such a brief outline of the very useful historical sketch which M. Dauhree gives as a prelude to the results of his own researches, which, after being continued for 40 years, and scattered through many publications, are now comprised in one volume. This will enable the reader more fully to estimate the value of his labors, and at the same time will materially assist the geologist who has not carried on similar work. The hearings of experimental geology may assist in explaining many of the chemical, physical and mechanical phenomena, which he meets with in the field, and the causes of which are difficult to understand, considering the complex subsequent modifications which have too frequently masked their primal origin.

The first section of the volume deals with chemical and physical phenomena in three chapters; wherein the author shows the application of the experimental method; 1st, to the history of the metalliferous deposits; 2d, to the study of metamorphic and eruptive rocks; 3d, to the history of volcanic phenomena. A portion of the second section, where the author describes the chemical decomposition of silicates, such as feldspar, by mechanical causes, in part belongs to the subjects discussed in the first section.

The history of metalliferous deposits is divided into (1) stanniferous masses, (2) "gites sulfures," commonly called plumbeous, (3) "gites de platine."

In dealing with the stanniferous group, M. Dauhree can point out how accurately he described in the *Annales de Mines*, nearly 40 years ago, the origin and constitution of tin deposits. The peculiarities of this group—so different

from the other, in which the electro-negative is mainly sulphur—arsenic noted; the mineral occurs as an oxide, and the gangues are not the same. The metalliferous fissures, too, are not like ordinary lodes in the proper sense of the term, but seem to be more like a number of small shrinkage cracks, and the neighboring rock is charged for some distance with the mineral (cassiterite). This network of small veins contains an enormous proportion of quartz, and the oxide of tin is further escorted by certain minerals unusual in ordinary lodes—such as topaz, pyenite, tourmaline (schorl), axinite and also apatite—so that the accompanying elements, besides silicon are boron and fluorine, and frequently phosphorus and arsenic, forming combinations which cannot be explained by these mere chemical analogies of these different elements, as is the natural association of iron with manganese, or cobalt with nickel. These observations have been supplemented in a recent contribution to the *Quart. Journ. Geol. Soc.*, by Dr. Ls Nave Foster, who gives some very interesting details, especially as to the fact of lodes containing from one to three per cent. of cassiterite, themselves consisting of schorl rock, which he describes as a matted mass of fine needles of schorl in a ground mass of quartz, with granules of cassiterite scattered through it, or arranged in little strings and veins. From these considerations it may be gathered that fluorine was the agent which performed at once the part of carrier and mineralizer, thus discharging the task allotted to sulphur in the plumbeous (sulphureted) group.

Fluoride of tin is a compound stable at high temperatures, and in all probability the tin came up as fluoride from the general reservoir of this heavy metal. Boron, too, has a tendency to combine with fluoride, and fluoride of boron being volatile would also ascend. In the artificial preparation of cassiterite, effected by M. Dauhree, as long ago as 1841, not having conveniences for the employment of fluorides, he brought together in a porcelain tube the vapor of hydrochloride of tin and steam at a temperature below 300° C. Small but well-formed crystals resulted, having a density of 6.72, and adhering closely to the sides of the tube. Similarly, by employing perchloride of titanium, he obtained small crystalline grains of titanic acid. The artificial production of apatite was affected by the action of perchloride of phosphorus, first on caustic lime and afterwards on chalk, the result being a true chlor-apatite. In these operations some chloride of silicon was formed at the expense of the porcelain. Thus he argues, that if the vapors of stannic chloride and fluoride, which appear to have formed the stanniferous deposits, were accompanied by perchloride of phosphorus, this latter, when encountering lime in the enveloping rocks, must have formed apatite accompanied by fluor spar.

Still referring to this subject, M. Dauhree, whilst apologizing for introducing his own work as that of a geologist rather than of a chemist, mentions that, 17 years after these experiments (viz. in 1850), Deville produced corundum by means of volatile metallic fluorides reacting on oxidized compounds, and that by means of fluoride of titanium Hantefeuille reproduced the three forms of titanic acid.

The sulphureted group, being the one in which the majority of metals occur, is not dealt with generally, but M. Dauhree points out the existence of analogous products of recent formation in warm springs, such as those of Bourbonne-les-Bains. An abstract of the author's paper in the *Comptes Rendus*, for 1875, has already appeared in this magazine. Bourbonne-les-Bains is not the only place where Roman coins have yielded metallic sulphides, but there the circumstances seem to have been peculiarly favorable, and M. Dauhree illustrates these by a series of cuts with much exactitude. Some 20 kilogrammes of bronze coins were found at the bottom of a Roman well (*puisard*), associated with black organic mud, where they had been bathed for 16 centuries by mineral waters at present containing eight grammes of solid matter to the liter, and having a temperature of 65° C. at the principal point of discharge. In a permeable bed towards the bottom were evidences of bronze coins, etc., which had undergone decomposition, more or less complete. Four species of cupric sulphide result. The tin appears as a white earthy crust, consisting chiefly of oxide. The lead pipes in place were coated with posgenite (carbonate of lead and chloride of lead), which, by the reducing action of organic matter in the presence of gypsum, has yielded small but definite crystals of galena.

Such an automatic laboratory, containing within itself a sort of electro-chemical apparatus, was a valuable legacy of the Romanized Gaul to his descendants, not to be appraised so much for its metallic worth, as for its utility in supplementing those essays in synthesis which the shortness of human life too often forbids to be accomplished within the limits assigned to one generation. We also learn in this case how Nature is gradually reversing the operations of man; remarking, as it were, those elements which had been divorced by the laborious operations of the miner and the smelter.

It is just possible that discoveries such as the preceding, confirming our knowledge of what can be done in the wet way in warm springs and mine-waters within periods short in a geological sense, may tend to exaggerate the importance of the part played by water as a solvent at a time when the great sulphureted lodes received the bulk of their metallic charge. These phenomena merely represent the final stages of processes infinitely more energetic.

M. Dauhree asks, what should we see if it were possible to descend the fractures serving as channels for the ascent of the thermal waters? We should probably find additional proof of the important modifications produced by water at increasing temperatures, but this would not lessen the probability that the metals associated with lead would have been volatilized from depths where no water is in combination with sulphur, selenium, tellurium or arsenic, just as he has shown how tin has been volatilized in combination with fluorine.

This second portion of the chemical and physical subdivision of the subject treats of the metamorphic and eruptive rocks, and of the application of the experimental method of their study. The author interprets the word "metamorphism," in its widest and most conventional sense; 1st, as simple molecular re-arrangement; 2d, as crystalline re-arrangement based on matter ready on the spot; 3d, as crystalline re-arrangement with importation of new or elimination of old matter.

Metamorphism of juxtaposition is the term he prefers for those modifications which are effected by invading rocks within moderate distances, though such modifications may reach as far as 3,000 meters in the case of granitic invasions. In dealing with regional metamorphism he expressly excludes the old gneisses and mica schists which underlie the stratified fossiliferous terranes, and confines his observations to the schistose masses whose metamorphic origin is, he says, clearly demonstrated.

This is certainly heaving a question which many persons would be loath to concede. This above quoted remarks were originally published by M. Dauhree, in 1859, and have not been altered in this present work, so that no reference is made to the numerous memoirs which have appeared since that date. It is clear that M. Dauhree still continues a strong believer in the doctrine of Epigenesis—that Hibernian form of metamorphism which is accompanied by considerable change of substance. It somewhat detracts, therefore, from the interest of this part of his work, that he has not thought fit to notice the numerous papers contributed to this subject of late years. We find him, for instance, stating that this modification (regional metamorphism), is easily recognized in such countries as Wales, the Tannus, and the Ardennes. Certainly the alleged metamorphism of portions of the former country has been disputed on good grounds by very competent observers, who, although they probably differ in details, have adduced most excellent evidences that certain beds of obscure origin are by no means the metamorphosed equivalents of beds elsewhere recognized as forming part of sedimentary formations of known age. We leave the Tannus and the Ardennes to this consideration of foreign critics.

In the Alps there seems to be better evidence of metamorphism as understood by M. Dauhree, but the strongest case is this well-known one in the Vosges, where, as observed by M. Delesse, the organic remains so well preserved at Rothau deserve to be considered as the classical monuments of metamorphism. Here syenitic granites has penetrated Devonian beds, which for several hundred meters from the point of contact are entirely modified. At certain points the altered rock consists of a compound of lamellar pyroxene, epidots and compact garnet, associated with abundance of fossil corals. The cavities bristle with elongated crystals of amphibole, etc. Such a case as this should in fairness be quoted under the head of metamorphism of juxtaposition; but anyhow it is a hard nut for those who disbelieve in the extensive alteration of sedimentary beds to crack.

The causes of metamorphism are next considered, and here it is again evident that change of substance as well as of form is the kind of metamorphism most frequently present in the mind of the author. Heat (which is from two sources), even when aided by certain vapors, is not sufficient; we must, then, look to water as having performed an important part "dans les phenomenes metamorphiques aussi bien que dans les eruptions des volcans." This requires to be further supplemented by pressure.

It became necessary, therefore, in the application of the experimental method, to ascertain how far heat, water and pressure could be made to reproduce the principal phenomena of metamorphism. The means to effect this are shown in a series of illustrations, the general principle being to operate upon a glass tube placed inside one of iron. The tubes were exposed to a temperature of about 400° C. during several weeks. It was found that pure water suitably superheated will transform an anhydrous silicate, such as glass, into a hydrated silicate of zeolitic character. A glass, for instance, containing silica 68.4, lime 12.0, magnesia 0.5, soda 14.7, alumina 4.9, was found to lose silica, alkali and alumina, whilst the relative amount of lime seems to have increased, and the new silicate had a fixed quantity of water.

The results varied according to the different nature of the glass, and of the substance added to the water. Crystals of quartz were frequently formed. The weight of the water which effected all these alterations was only one-third of that of the glass transformed. Obsidians and perlitic were also tried with partial success; some crystals of feldspar and pyroxene associated with these underwent no alteration, but were "sugared" over with little crystals of quartz. M. Dauhree enlarges on the wonderful results which have thus been obtained in the wet way, even to the production of an anhydrous silicate, such as pyroxene, at temperatures

far below the fusing point of the mineral. The application of these results to the phenomena of metamorphism is obvious, and explains, amongst other things, the ready liberation of silica from compound silicates, the formation of quartz on a large scale.

The Roman masonry at Plombieres and elsewhere, so long in contact with warm mineral springs, affords an admirable instance of "contemporaneous metamorphism." The reaction of the alkaline waters upon the mortar and bricks has resulted in the deposit of chalcedony and of many zeolitic minerals. Microscopic sections of bricks with geodes lined with chalcedony, etc., afford very effective pictures, and many interesting chemical details are added. The curious white concretionary substance called *Plombierite*—gelatinous when moist, and transported and deposited by the water like silica itself—appears, according to Fouque's analysis, to be compound or mixture of carbonate and silicate of lime with water. All these results have been effected at moderate temperatures and without pressure. A valuable digest of these facts appeared in the *Quart. Journ. Geol. Soc.* for 1878 (vol. xxiv.), where M. Dauhree observes that zeolitic minerals may be considered as a kind of "extract" of the rocks that have been subjected to a continued lixiviation.

Water, he therefore insists, has played an important part in the crystallization both of eruptive end of metamorphic rocks, especially as it permits the crystallization of silicates at temperatures far below their fusing points; we must thus look to the hydrothermal rather than to the dry way for the explanation of the origin of silicates in a large part of the rocks.

Under these circumstances, and adopting the very comprehensive word "metamorphism" in the sense used by M. Dauhree, it will become more difficult than ever to distinguish between altered and erupted masses when viewed merely under their petrological aspects.

Not the least interesting of M. Dauhree's experiments was made with a view to determine how far the capillary infiltration of water could supply the immense quantities used in volcanic eruptions. A suitable apparatus enabled the author to demonstrate that liquid water will force its way through a slab of close sandstone against a very considerable pressure of steam. He therefore infers, that in spite of the powerful upward pressure of aqueous vapor, the cooler waters of the earth's surface do find their way through the rocks themselves, and that what is known as quarry water is nothing but this feeder surprised at the commencement of its downward journey.

The second section of the work, being devoted to mechanical phenomena, is worthy of a separate notice, but there are some subjects discussed which have a chemical bearing. Important experiments were carried on with a view to ascertain how far the decomposition of silicates is effected by mechanical causes. There is probably no question in the whole work which has a more important geological bearing than this, because it enables us to form some idea how the debris of crystalline rocks is chemically altered during the process of degradation. Dr. Sterry Hunt has always emphasized this point, and those who question the wholesale introduction of fresh matter into rocks which the ultra-metamorphic school have taught, attach much weight to their chemical composition as controlling the possibilities of alteration.

Orthose in fragments was rotated in a cylinder along with distilled water. When the experiment was performed in an iron cylinder, 3 kilogrammes of feldspar, after a journey equal to 460 kilometers, yielded to 5 liters of water 12½ grammes of potash, with very small quantities of silica and alumina. To effect such a decomposition mechanical division and the solvent action of water must be exercised simultaneously. Curiously enough the presence of chloride of sodium arrests the decomposition. The presence of carbonic acid facilitates the solution, and much silica, as well as potash, is dissolved. Obsidian and leucite are but slightly attacked. In these operations the mud obtained is in such a fine state of division as to render the liquid opaline, and it takes some days to settle: the quantity of potash retained is still very considerable. Such a substance would form the "phyllades" or argillaceous schists which occur in the stratified terrance at different geological stages: these often contain from 6% to 7% of potash.

Finally, M. Dauhree once more returns to the subject of metamorphism, and having observed that dry clay triturated against itself, had its temperature raised in three-quarters of an hour from 18° C. to 40° C., speculates on the possibility of the transformation of mechanical force into heat in regions such as the Alps, during the period when those forces acted with the greatest intensity.

A UNITED STATES patent has been granted to A. E. Mery, of Paris, for a composition for applying colors, specifying the following ingredients: Glycerine, 25 parts (by weight); glycerine, 534 parts; water, 203 parts; white wax, 203 parts; strong solution of ammonia, 12½ parts, and usin, 12½ parts, dissolved in ether. Any coloring matter may be mixed with this paste, thereby forming a paint.

BICHLORIDE of mercury, known commonly by the name of corrosive sublimate, will remove the stains of nitrate of silver.

FRANCE annually makes 750,000 tons of excellent fuel from the dust of her coal mines.

*Etudes Synthétiques de Géologie expérimentale. Première partie. Application de la méthode expérimentale à l'étude de divers phénomènes géologiques. Par A. Dauhree, Sec. (Paris, 1879.) Reviewed by W. H. Hudleston in the *Geological Magazine*.

Red Canyon Mines, Nevada.

In consequence of some very rich gold rocks and other indications found at this place, which lies 35 miles east of south of Virginia City in a direct line of 45 miles by road, it is supposed this mother lode has been discovered. The *Gold Hill News* of the 6th inst. says on the subject generally: On the table before the writer is a specimen of gold rock from one of the new finds which is fabulously rich in free gold. It was taken from a large specimen in Virginia, which is better than the piece secured. It is so fine a specimen of gold quartz that it is useless to assay it. It was sent in by Bob Morrison, and was taken from an unnamed extension of the Hester Holbrook claim. It came from a ledge three feet in width of milling rock. Of this width, six inches next the hanging wall are of the rich rock shown. Free gold is found in large quantities all through the vein.

In the immediate vicinity of the new find are Gray & Carter and the Golden Belt claims, which with the Hester Holbrook are the principal locations of the section. The portion of Red canyon in which these mines are located has plenty of water to run mills, and reducing machinery and one arastra is now running on Gray & Carter rock, but has not yet cleaned up. The mine from which the specimens were sent is being developed by a few men on their own account. If there is as much rock there of the quality before us as is reported, they will have all the money they want.

Persons who are inquiring the route there may be interested in the following, which will be found to be tolerably correct. From Dayton the road leads up El Dorado canyon about eleven miles to the signboard. Here the fork leading up Pine Nut valley is taken to the head of that valley, about seven miles. At this point the left fork of the road is followed some eleven miles to the Winters mine. This is the beginning of the mining section. Thus it will be seen that the camp lies about on the line run out by "Old Man" Gould, in the early days of the Comstock, as the trend of the mineral bearing belt here encountered.

The section reached as above is rough enough for the delight of all prospectors. From the Winters mine, one road takes up to the top of the ridge—the highest in the section—and leads to the center fork of Red canyon. Another road keeps up the principal ravine and some six miles further on are found the group of mines which includes the new find. They lie at the head of the canyon, and near them comes in the road from Carson. A little further east is the silver mine of Gray & Carter. The section is also very readily reached by the prison road from Carson. Red canyon is a sort of pass across the ridge, and after reaching up towards the top bends to the east and runs down toward Wellington's station. But the mines above-mentioned lie west of the summit and on the western water-shed.

Just at present the excitement is over the gold rock of the section. There are, however, some cool heads in that section who have been searching for something further. N. B. Daniels, of Virginia, is one of these, and he and R. M. Ballard, foreman of the Ophir, think they have found the mother lode, a silver-bearing vein some four miles further along on the eastern slope and near the summit of the make of land. This lode is, on the surface, 100 ft in width. A shaft has been sunk on it 30 ft and it has been found to be well defined and the ore assays from \$40 to \$300. Locations have been made and holding work done, and now they are waiting for another season in which to more fully prospect their claims.

FRENCH IMITATION OF GOLD.—One of the most remarkable achievements in the production of an alloy for perfectly imitating gold, is said to have been made by M. Meiffren, of Marseilles, the alloy standing a very acid test, and its specific gravity being also extremely close to that of gold of the fineness indicated by the acid test—being, therefore, peculiarly adapted to the manufacture of jewelry. The method of production in this case is to place in a crucible, copper as pure as possible, platinum and tungstic acid in proportions as follows: Copper, 800 grammes, 25 of platinum, 10 of tungstic acid, 175 of gold; when these metals are completely melted they are stirred and granulated by being run into water containing 500 grammes of slacked lime and the same of carbonate of potash for every cubic meter of water, this mixture, dissolved in water, having the property of rendering the alloy still purer. The granulated metal is next collected, dried and, after remelting in a crucible, a certain quantity of fine gold is added. In this way an alloy results which, when run into ingots, presents the appearance of red gold of the standard of 750-1,000ths. The color of the alloy may be changed by varying the proportions of the different metals. As a flux, boracic acid, nitrate of soda and chloride of sodium, previously melted together in equal proportion, are used, the proportion of flux employed being 25 grammes per kilogramme of the alloy.

ALMOST the universal article used on the continent for kindling fires are dry pine cones. A couple of these are usually enough to start a fire of dry wood, and several of them contain enough resinous material to start a coal fire without other kindling. They are readily lighted with a match, and are free from dust and insects. In Paris and other large cities on the continent scarcely any other than pine cones are used for kindling purposes in the hotels.

USEFUL INFORMATION.

TO ESTIMATE THE CONSTITUENTS OF CEREALS.

Messrs. Hayes, of Roxbury, and Jackson, of Boston, Mass., have discovered a way of measuring approximately the valuable constituents of grains. If a kernel of corn be split longitudinally, and immersed in an aqueous solution of sulphate of copper, the germ, or "chit," only becomes colored green, thereby beautifully defining the limits of the phosphates by the formation of phosphate of copper. If a kernel of corn be split open and thrown into a solution of sulphate of ammonia, the "chit" will soon be changed to a dark olive color, which is due to a change of the salts of iron in the seed to a sulphuret of that metal; a dark-colored matter forming with the ammonia turns the vegetable coloring matter yellow, and the two colors combined produce an olive. Again, by taking split specimens of corn, or other grains, and soaking them in a tincture of iodine, the limits of the starch and dextrine will be distinctly defined—the iodine striking an intense blue with the starch, and a deep port wine red with the dextrine; so that, from this test, a rich violet (being the combination of the blue and red colors) will indicate the presence of both the starch and dextrine in the grain. If the oil be extracted from the transparent horny part of the corn by means of alcohol or ether, the tincture of iodine will show the presence of starch in that part of the grain associated with the gluten. By these means we may easily cause any of our cereal grains to represent to us the extent and precise limits of its phosphates, iron, dextrine, starch and oil; and thus, by the eye alone, we may form an approximate estimate of the relative proportions of these ingredients.—*American Miller.*

DESTRUCTION OF FIRE-DAMP.—A mining student of Freiberg has invented an improved lamp for the protection of life against explosions of fire-damp. It is based upon the property possessed by ethiops of platinum of condensing on its surface not only oxygen but also light carbureted hydrogen, even when only small quantities of it exist in the atmosphere, and in this close contact of the two gases effecting a dark combustion of the carbureted hydrogen. A wire gauze lamp is charged with pieces of pumice stone, impregnated with ethiops of platinum. These lumps are surrounded by coke to protect them, and enclosed in the lamp, which is then ready. In the presence of fire-damp the ethiops of platinum attracts the gas, which is gradually and harmlessly destroyed, the consumption being within this gauze and not of a nature to ignite a surrounding explosive atmosphere. Mr. Korner, the inventor, points out that a great advantage of this safety inflammable air-consuming lamp consists in its not requiring continuous attention and maintenance, as the ethiops of platinum will consume a large quantity of the light carbureted hydrogen without losing its properties. Control of the lamp is effected through the escaping heat. Lamps as described may be advantageously used in all places where there is inflammable air.

MEATS COOKED BY COLD.—It seems unlikely at first thought, yet it is a fact that extreme cold produces in organic substances effects closely resembling those of heat. Thus, contact with frozen mercury gives the same sensation as contact with fire; and meat that has been exposed to very low temperature assumes a condition like that produced by heat. This action of intense cold has been turned to account for economical uses by Dr. Sawiczewsky, a Hungarian chemist, as we learn from *La Nature*. He subjects fresh meats to a temperature of minus 33° Fahrenheit, and having thus "cooked them by cold," seals them hermetically in tin cans. The results are represented as being entirely satisfactory. The meat, when taken out of the can a long time afterward, is found to be, as regards its appearance and its odor, in all respects as inviting as at first. A German government commission has made experiments with this process, and in consequence two naval vessels dispatched on a voyage of circumnavigation were provided with meat prepared in this way. Hungary has an establishment for preserving meats by this process.

TREATMENT OF NEW WOODEN UTENSILS.—Wooden vessels for containing articles of food, wine, etc., also wooden vessels for culinary purposes, can be rendered fit for immediate use by the removal of the unpleasant extractive matters by treatment with a solution of washing soda, thus: An ordinary barrel should be filled half full of water, and a solution of about two pounds of soda in as much water as will dissolve it poured in, and the liquids thoroughly mixed by shaking the barrel, which should then be filled to the bung with water, and allowed to remain from 12 to 14 hours; then, after withdrawing the discolored liquid, it should be well rinsed and filled with pure water, and should remain a few hours more, when it will be fit for use. Other wooden utensils may be similarly treated.

POTATO BUGS UTILIZED.—Those who like to find "good in everything" will be gratified to learn that it appears from experiments described in the *Journal of Pharmacy* that the fresh powder of the potato bug yields about 1½% of pure cantharidin. This is a large product, and no doubt these pests will be increasingly used as a cheap source of this valuable remedy.

SOMETHING NEW IN BOILER MAKING.—We learn from English journals that a few weeks ago a number of engineers visited the Park View steel works, Owlerton, near Sheffield, for the purpose of seeing Mr. George Whitehead's new process for producing weldless and seamless steel and iron boilers. A ring of steel is cast and heated. Then it is placed upon a large roller, and by the aid of smaller rollers it is enlarged to the requisite dimensions. The ring is run from one end of the roller to the other, and is returned by a reversing of the machinery. The other portions necessary for the completion of the boiler are subsequently put on with bolts. Mr. Whitehead states that boilers constructed on this process will stand twice the pressure of those made of riveted plates.

A NEW CEMENT.—Asbestos powder made into a thick paste with the liquid silicate of soda, according to a leading English authority, is stated to be found to be of great advantage for making joints, fitting taps, connecting pipes, and filling cracks in retorts. It is said to be of great service in the manufacture of nitric acid, sulphuric acid, and other products, because it can be as easily made as applied, hardens rapidly, and prevents the escape of acid vapors.

NEW COLORING MATTER.—Mr. T. L. Phipson reports to the French Academy of Sciences the discovery of a new rose-red coloring matter, which he has succeeded in extracting from the little blood-red alga, found at the base of damp walls. It resembles no other known color, and exhibits considerable analogy with the hemoglobine of the blood. It is the first time that a substance of this kind has been met with in the vegetable kingdom.

A NEW CARBAZOL FROM COAL TAR.—C. Graebe and W. Knecht. This compound, for which the authors propose no name, is represented by the formula $C_{12}H_{11}N$. It melts at 330°, dissolves scarcely if at all in cold alcohol and benzol, sparingly in boiling benzol and glacial acetic acid. It is moderately soluble in hot aniline. The solution has an intense blue fluorescence.

GOOD HEALTH.

Water Infection in Diphtheria.

Dr. Benjamin Browning, the Health Officer of Rotherhithe, (London), has an interesting paper on this subject in the *Sanitary Record*. He gives a variety of cases, occurring in city and rural districts, which appear to prove beyond a doubt that diphtheria may be caused by polluted water. The disease has been found to prevail in families using the water, while their neighbors who did not use it, but who were otherwise exposed to the same chances of infection, were exempt. In one instance he met with seven cases of diphtheria in the family of a railway station-master. He says: "I could ascertain no previous contagion, but found the existence of the customary polluted shallow well, close to the public latrine, the whole premises being isolated, standing on a lofty chalky embankment. Two casual visitors to the station (not to the dwelling-house) who drank some water in the waiting-room also contracted the disease. There was no more of it before or afterwards in this parish while I knew it."

Dr. Browning seems to have been careful to satisfy himself that the disease could not have had any other origin than the bad water. On this point he says:

"In the country epidemics I have mentioned, at their commencement, no direct personal contagion could be made out, although it was anxiously sought for; aerial infection seemed everywhere contra-indicated, owing to the open and breezy situation of nearly all the implicated dwellings; in all of them the drinking water was organically impure, and received surface filth of every description; and in the town cases there was also clear evidence of water pollution by sewer-gas or fetid emanations, if not by actual deposit of dirt. And I venture to submit that I have therefore supplied some of that 'evidence,' which is by Dr. Parkes and others deemed 'still wanting,' to prove the 'production of diphtheria by contaminated water.'"

Not satisfied, however, with this logical evidence, Dr. Browning determined to settle the question by direct experiment upon the lower animals; and he actually succeeded in infecting two kittens with the disease, by feeding one with milk mixed with water in which he had kept diphtheritic false membrane and sputum, and the other with milk adulterated with water taken from the cistern of a house where a fatal case of diphtheria had recently occurred. Microscopic specimens of the diphtheritic membranes from these animals were shown at a meeting of medical gentlemen, none of whom were committed to Dr. Browning's theory, and pronounced by them to be identical with specimens taken from human beings. If this testimony is not accepted as conclusive, it must at least be admitted that it is of sufficient importance to show that further experiments and investigations should be made in order to confirm or refute it.

A PLEASANT REMEDY FOR TOOTHACHE.—Dr.

T. C. Osborn, in the *Medical Brief*, states that his cook came to him with a swollen cheek, asking for something to relieve the toothache with which she had been suffering all the night. He was on the point of sending her to a dentist, when it occurred to him that there was in the house a vial of compound tincture of benzoin. "After cleansing the decayed tooth," he says, "I saturated a pledget of cotton lint with the tincture, and packed it well into the cavity, hoping this would suffice for the time, and told her to come back in two or three hours if she was not relieved. I was turning away, when she said it might not be necessary, perhaps, as the pain was already gone. Supposing her faith had a large share in the relief, I would not allow myself to think that the medicine had anything to do with the cure any more than so much hot water would have had. But when I arrived at my office, two other patients were awaiting me with the same affliction, and I determined, by way of experiment, to use the same remedy. To my agreeable surprise both patients declared themselves immediately relieved, and begged a vial of the tincture for future use. During the winter a number of similar cases applied, and were instantly relieved by the same treatment, all expressing much satisfaction with the remedy. In December I told my druggist of the discovery, and recommended him to sell it to any person applying for 'toothache drops.' This, he reports, he has done, and that every one seems delighted with the medicine."

REPLANTING TEETH.—G. W. Weld, dental surgeon, recently read before the First District Dental Society of New York a paper on the subject of replanting teeth. The root of the tooth is first extracted and the decayed portion cut squarely off at or directly under the margin of the gum. A porcelain crown with a tapering screw made of platinum and iridium, which had been securely baked in the center perfectly parallel with its length, is then firmly screwed into the pulp canal of the root, the nerve having first been removed and the canal enlarged by reaming out with an engine-reamer. To facilitate the introduction of the screw, a preparatory thread is cut in the root with a tap. This process establishes a very strong attachment between the natural root and the porcelain crown, and with the additional aid of cement in the canal, it is made perfect. When this operation is completed (which requires from 15 to 20 minutes) the socket is syringed out with tepid water, and the root with the new crown attached is gently but firmly pressed into its original position. Perfect reattachment ensues in from two to four weeks. There is seldom any pain attending the operation, and very little inflammation.

PHENIC ACID AND YELLOW FEVER.—A French physician, better known as the heir to the once famous Duke of Gramont-Caderousse than in the capacity of a practitioner, Dr. Declat, has just completed by proxy, at Senegal, experiments on the treatment of yellow fever, with apparently very satisfactory results. Dr. Declat, has been led to infer theoretically, from the symptoms of the disease that phenic acid might be used in such cases with some probability of success, as a prophylactic as well as a remedy. Some months ago he forwarded a dozen bottles of the compound to a missionary, with practical instructions as to its use, and the request of a report on the facts. The missionary, who seems to be a clever, enlightened man, with some knowledge of medicine and considerable experience of yellow fever, now writes that not only did he actually rescue from imminent death by dint of the remedy several natives who were writhing under the pangs of the disease, but he himself owes his life to its use. This, indeed, if confirmed on a large scale, would prove a boon to America and the west coast of Africa.

ANOTHER CURE FOR SEA-SICKNESS.—A writer, Mr. Chapham, says in the *London Lancet* that nitrate of amyl is a sure cure for sea-sickness. "With due attention to details the drug is curative in at least 90% of all cases treated." He directs that not more than three drops be taken at a time, inhaled from a handkerchief held close to the nose. It should not be used except under medical advice. The patient when under this treatment should lie in bed, because a good sleep is generally the first result, from which the person awakes wanting to eat. It is usually better to allow one fit of vomiting to occur before the treatment is commenced, "to insure the bona fide character of the seizure." Some, however, do not vomit at all, but are very ill, and with these Mr. Chapham considers the nitrate equally successful.

LAXATIVE BREAD.—Mr. W. H. Taylor states in the *London Lancet* that he has lately had bread prepared as follows, and it found it most useful in ordinary constipation, and as a laxative in piles: Coarse Scotch oatmeal, whole wheat flour, coarse ordinary flour, of each equal parts. The bread can be lightened by yeast, or to a two-pound loaf, one tablespoonful of baking-powder, made of four ounces of bicarbonate of soda, three ounces of tartaric acid, one pound of ordinary flour, rubbed well together, and kept dry in a tin or well-cooked bottle. The bread keeps well, and a two-pound loaf will be sufficient for a week, taking a portion once or twice a day in conjunction with ordinary bread.

The Week.

One of the indications of returning prosperity is the advance in price of all kinds of merchandise. The mere fact that goods are being marked up does not indicate anything except when connected with the prices ruling at supply centers, which is now the case, and shows an increasing demand. Iron, nails and tinware have risen fully 50%, while lead and quicksilver have gone up proportionately. Even silver has felt the movement and have an upward tendency. Snow has already made its appearance in the mountains in sufficient quantities in some places to compel a suspension of mining operations, particularly around Leadville, Colorado, where, in the mountains, the ground is covered with from two to eight feet of snow. The various mining industries are prosperous, with the exception, perhaps, of some of the hydraulic mines in this State which are afflicted with restraining orders from the civil courts.

The strike on the 2100 level of the Hale and Norcross discloses the fact that there is a rich vein of ore there with every indication of permanency. That, of course, taking the reports to be true.

The railroad projects of the country are advancing steadily. Jay Cooke has been able to pay nearly all of his indebtedness by reason of the recent advance in Northern Pacific. The Southern Pacific is pushing towards Mesilla, while the Texas Pacific is building towards the Pacific. The Atcheson, Topeka & Santa Fe has its eye on San Diego as a terminus. All of these different railroads will soon converge at some point not yet known to the public. The country in the meantime is improving its prospects, and the means of transportation speedily being afforded to heretofore remote and inaccessible regions will open up new avenues of trade and commerce, which must, to a great degree, ensure to the benefit of the Pacific coast generally.

An Accurate Mine Survey.

A very difficult piece of engineering work has recently been accomplished at the New Almaden Quicksilver mines by Hennen Jennings, C. E., the facts in connection with which will be of interest to mining engineers. Connection has been made between the Randol and Santa Isabel shafts on the so-called 1700 level, the survey being made under peculiar difficulties, but with strikingly accurate results.

The horizontal distance between the Randol and Isabel shafts is 1,280 feet, and the difference of level between their collars 300 feet. The connecting drifts were started on the same level from these shafts. From the Randol 1,223 feet below, and from the Isabel 927 feet below the collar. There is a tunnel connecting the surface with a point of the Randol shaft 331 feet below its collar, and it was through this tunnel that the deflection lines were carried, and from this level that the wires were suspended. Both the drifts below and the tunnel above were run partly on a curve, and, as the surface passed over was mountainous and abrupt, it was necessary to make 17 angles in the circuit. The total length of circuit (horizontal length) was 3,468 feet, 1,337 feet of which was on the connecting drifts, connection being made 430 feet from the Isabel shaft.

The main difficulty encountered was one which is seldom met with in so appalling a form in mine surveying, viz: that of projecting a 2 foot 7 inch base line 900 feet down a vertical shaft by means of two plumb lines disturbed by falling water and strong currents of air. Such was the case in the Randol shaft. The base in the Isabel shaft was 3 feet 4 inches, and the distance plumbed, 940 feet.

For plumb lines Mr. Jennings used the finest quality of steel piano wires one-fiftieth of an inch in diameter, and without splice, suspending them above the point of observation at the top. Attached to these at the bottom were 18 pound plumb-bobs submerged in molasses.

The apparatus used to suspend these wires and to shift them into any required position was introduced here by Hamilton Smith, C. E., and is exceedingly convenient in its details.

The transit used to prolong the line defined by the two suspended wires was provided with a slide plate movable by two slow-motion screws.

In order to prolong this base line into the drift, the transit was placed in approximate line with, and about 14 feet distant from, the wires. By means of a prolonged and pains-taking study of the oscillations of the wires and a corresponding shifting of the body of the instrument on the slide plate (by means of the slow-motion screws) the line of collimation of the instrument was eventually made to pass through the average of the oscillations of each wire, and thus the base was prolonged.

Considerable time was consumed in placing the wires and prolonging the base. In one instance 23 hours were spent in doing this in the Randol shaft.

The result of this survey was very much more accurate than Mr. Jennings could have anticipated, considering the difficulties under which the work was carried on.

The error of alignment was 0.45 of a foot; the error of distance, 0.49 of a foot; and the error of level only 0.025 of a foot.

In order to weigh the accuracy of this result, suppose in determining the average of the oscillations of one wire in the Randol shaft, an error of 0.01 of a foot had occurred, all of the rest of the work being perfect, the error of alignment at the point of connection would have then amounted to more than 3½ feet.

F. Von Leicht, C. E., checked the survey shortly before connection was made. Mr. Jennings says that he profited to a considerable extent by the experience of Mr. Ross E. Browne, his predecessor, having acted as Mr. Browne's assistant for a year previous to undertaking this connection, in similar, though less difficult work.

NEW JOURNALISTIC VENTURE.—*La Sonora* is the title of a little weekly just started at Tucson, Arizona, under the editorial management of Mrs. Josephine Lindley Corella. The growing social and commercial relations between Arizona and the State of Sonora suggested the idea of publishing a paper in Spanish, with occasional articles in English, to serve as an interpreter between the two countries; "a paper that, by endeavoring to destroy old prejudices and explain misunderstandings, shall strive to give both peoples, Americans and Mexicans, a better knowledge of each other." Mrs. Corella, the daughter of Judge Lindley, formerly of Los Angeles, is an intelligent and accomplished woman, well fitted, we believe, to succeed in her praiseworthy undertaking, and we extend to her a cordial welcome and Godspeed.

NOTIFICATION has been received at the Post-office Department that the Republic of Venezuela has become a member of the Universal Postal Union, to date from the 1st of next January.

SILVER in London 53½d; consols, 97 15-16; 5% United States bonds, 105½; 4s, 106; 4½s, 109½.

Growth of Mining Interests.

It is a patent fact that large sums of money have been, and are now being, invested by prudent capitalists of this country and Europe in mining securities, and it is certain that large sums in the future will seek our mines as one of the best investments and well calculated to bring the best returns. The inducement which is now leading capitalists to resort to this species of investment is undoubtedly founded upon the gradual growth of the business as a legitimate industry. The history of every gigantic business, where wealth was to be speedily developed, was cradled in many unfortunate bubbles which operated to the injury of many from a too hasty desire to reap in the present the rewards which the future alone could promise. But experience, that school of wisdom, eventually dispels the glare of mere speculation and, grasping the reality of the scheme, forces into it an element of solidity which belongs to it, and the wild exaggerations engendered in the imagination become things of the past.

According to the records in 1853, \$65,000,000 in gold were produced in this country; in 1854 only \$60,000,000, and in 1857 only \$55,000,000. During three years there is no account of the silver production. Our official records are a blank, our total bullion products are in the most precious yellow metal. In 1858, however, the official estimate is \$500,000 for the production of silver and \$50,000,000 for the production of gold. In 1859 the silver production was only \$100,000, and in 1860 only \$150,000. In 1861, however, there was \$2,000,000 of silver produced to \$43,000,000 of gold, and in 1863, \$5,500,000 in silver to \$40,000,000 of gold. The proportion of silver has been gradually rising, until in 1873 it reached nearly \$36,000,000, while the gold product was a trifle more. In 1878 the silver production was \$41,000,000, and the gold production \$50,000,000. It will be noticed that in the figures that we have given that the proportion of silver to gold is gradually rising, and no doubt, in the not distant future, the silver product will be larger than the gold product of the country. Indeed, it must be borne in mind that the gold product of the world is decreasing. There is probably less gold in circulation to-day than ten years ago. Indeed gold was always the more fluctuating metal, being more often found in greater quantities, and then the supply suddenly ceasing, but the production of silver in this country, while it has been steadily rising, presents a uniform advance and takes no step backward.

We speak from the records of the past, of course, because we cannot foresee future discoveries, which may cause the balance of metal to fluctuate largely toward the side of the gold product. It is safe, however, to assume our premises as the results of actual experience. Another very important point which is almost a revelation to capitalists, is that mining is rapidly assuming the characteristics of a science in which skill has all to do with the successful and steady development of wealth where chance heretofore has been the guiding star.

The immense and never-ending supply of all the precious metals existing in our midst is a new feature in the business of the world. Of course, mining has always been carried on, but there has existed a vague impression, engendered probably by lack of knowledge, that the supply of gold and silver would become inadequate for the world's needs. But our comparatively recent developments have dispelled this illusion, and the business takes its place in the commerce of the world as the most enduring industry—an industry which will continue for all time, and founded upon that greatest of all foundations when human affairs are considered, universal demand. There is, too, a manifest lessening of distrust in the business, inasmuch as it has been demonstrated beyond a cavil, that it can be carried on properly so as to be relied upon as certainly for good returns as any other business.

The various disasters of trade and commerce, the depressions of business affecting the merchant; early frost and summer drouth destroying the best laid plans of the farmer, are absent in the mining business. The miner can determine accurately whether it will pay to work his mine, and having learned this, he may begin his labor, or make his expenditures without any misgivings.

In placer ground the miner sinks his shafts and prospects the dirt, and carefully examining the whole ground before putting in his flume, he knows how much dirt can be run off in a given time, and can estimate very nicely what every square yard of it will pay.

In quartz the prospector who sinks his shaft and runs his level can, if he is careful, know about how much his ore will pay above all expenses. Of course there may be slips, the placer ground may be unusually spotted, and the value of the sampled and assayed ore may be treated as an infallible guide to the whole. But common sense and discrimination are required in every business, and not less in delving for the precious metals. Nature is not capricious, but works according to rules which are invariable. Breaks and faults in her system are not mere accidents, but the results of other well-known and ascertainable laws. It is true that millions of dollars have been wasted in the erection of costly works upon the strength of mere surface indications, but these are the blunders of incompetency and not the fault of the business. The time has passed we trust when serious mistakes involving great loss will be made.

The Divining Rod Again.

The researches made by science have resulted in the establishment of exact rules for the ascertainment of what exists beneath the soil, whether mineral or fluid, that, so far as the former is concerned, there need not be any mistake if all of the "indications" are carefully studied, examined and compared. Quackery, however, has often, and will undoubtedly in the future, impose upon the unsuspecting, who do not think of comparing the relations between cause and effect. The forked stick called the divining rod has over and over again been explained; yet a greater power is sometimes accorded to this inanimate, unthinking and unreasoning piece of inert matter than would be believed possible, if the facts were known. It has been used to find subterranean streams, and we may with certainty say that every individual that places any confidence in the humbug is either interested peculiarly in it or has accidentally found a water-course where the rod pointed downward. It now comes up in the shape of a gold ledge-finder, notably in the recent development of the San Geronimo mine, in Marin county. The *Journal* says upon the subject: The history of the discovery of this mine is peculiar, and will achieve a wide notoriety if the mine turns out according to its present promise. Mr. Peck is the owner of a miner's divining-rod, whatever that may be. We have talked with several gentlemen who have seen it operate, but neither of them could explain the principle of its working. It consists of a bulb, the contents of which are unknown; this bulb is held firmly between two whalebones, and when carried over an ore-body will be strongly attracted, as a needle to a magnet. Mr. Peck's first intimation of this mine was received from the operation of his divining-rod, while passing it on the cars. Afterwards, going over the ground, he became satisfied that a rich mine existed there. He had great difficulty to enlist capital to open it, and labored about eighteen months before he succeeded. The gentlemen who then took hold of it, Messrs. Higgins and others, commenced their expenditures on the strength of the actual prospect, which was remarkably good, and which has improved steadily through more than a year of active delving in the ledge. The owners are now perfectly sanguine that they have a bonanza, and that in less than another year they will be operating mills on their ledge, and have five hundred men employed. It is said that Mr. Peck discovered, in the same way, a ledge in or near the North Con. Virginia, which he claimed would turn out a bonanza, and it proved true, as the Union Con. testifies.

We have this to say in regard to this divining-rod business:

First—If any essential virtue exists in the forked stick, or whalebone, with or without a bulb, the contents of which might be either known or unknown, it would infallibly act in the presence of any and every mineral vein or subterranean water-course, because it would be its nature to so act, and being inert matter any inherent law is bound to manifest itself when opportunity presents. But it does not possess any inherent virtue for the reason that it does not act even when held over known mineral veins.

Second—There is no connection between such an instrument or hulk and mineral veins, and consequently has no *raison d'être*. If there is any connection between the hulk and the vein it must be one of attraction; and like the magnet would act on every occasion in the same way and make its attraction manifest. But it does not do this. It fails to indicate the presence of well-known veins, as we said before.

Third—The secret of it lies in the power of the human mind over matter. From surface indications, the individual who holds the instrument in his hands, is persuaded that a vein exists, and the nervous ganglia acting upon the human muscles produce a contraction which acts upon the piece of matter held by him. So the divining-rod turns only when held by a person who believes he has found the vein. When held by an unbeliever it does not turn. But when it does turn the chances are against finding anything.

Planchette was of a similar nature, the power of the will acting upon the physical system caused the heart-shaped instrument to write his thoughts. It is not the instrument that possesses any virtue, but the influence of the mind which determines the peculiarity of the movement. The divining-rod has been used in the oil regions of Pennsylvania to find oil deposits, and in some localities there, hardly a square rod of ground exists without an underlying deposit of petroleum. So in our mineral regions where the indications are geologically strong, the person holding the rod would become perfectly convinced that there was a vein or ore of some kind, and might turn.

Fourth—If the rod is certain why is it not used to unlock the secrets of nature? Why wait eighteen months for capital to develop one single point in a vast mineral region? And if uncertain as in its nature it must be, then it is worthless, and it would be a delusion to rely upon it.

The Texas Pacific Railroad Company announces its intention of completing the road without asking for Government aid.

A Thoughtful Government.

The Washington correspondent of the Salt Lake Tribune, in a recent letter to that paper, gives an interesting sketch of the secret workings of land claimants. The writer says that under the law of 1850 there was issued from the Interior Department in October 27th last, about 100 military land patents for service rendered in almost every scrimmage in which the United States has ever been engaged. There were patents for services as volunteers and regulars rendered in the wars of 1812-14, Creek war, Cherokee war, Black Hawk war, Florida war, and one for service in "the Indian war," whatever that may mean. He says further: "In looking over these patents I could not find half a dozen in the name of heirs of the soldiers, but they were almost invariably 'only signed' to somebody else. And another peculiarity was that every acre called for has been located in the agricultural lands of the auriferous State of California." It is very fortunate that the State of California is of respectable dimensions, any common-sized State would long ago have been swallowed up. We cannot say we are sorry that these claims should be located in California, because it affords a proof that we are well thought of. The reason why some of these claims are not plastered on Utah or Colorado, etc., is not given, but we presume that the claimants having already survived several "bloody wars" for the commonwealth, prefer to settle in a peaceable community where there is no discount in scalp. Seriously speaking, however, some of these land schemes are mysteries, for instance:

"Some years ago—just to be definite I will say three—a score, more or less, of men, including attorneys, land agents, etc., entered into a combination to pre-empt as land belonging to the general Government and never disposed of, Dearborn Park, containing 300 or 400 acres, and about one-third also of the city of Chicago. They paid for it in what is officially known as 'Valentine Scrip.' The history of this scrip (and this is important to the story) is, one Valentine owned or claimed to have owned a 'Mexican Grant' of land which the Government had sold as its own. At all events, whether he ever owned such grant or not, he convinced a majority of Congress that he did, which is all the same, and that body passed a law giving him land scrip for the number of acres alleged to have been wrongfully disposed of by Uncle Sam's agent, with the privilege of locating it upon any unoccupied land belonging to the Government. The 'find' in Chicago was a very valuable one; well, there is or was 'millions' in it; indeed several of them, if the claim pans out well. Thus armed and equipped they appeared in due time at the General Land Office, and the then Commissioner, being in amiable and liberal mood, decided in their favor as demanded. Some busy-bodies in Chicago, in a moment of virtuous indignation, appealed the case to the Secretary of the Interior, who reversed the decision of his Commissioner, and for the principal cause that the Valentine scrip could only be used to take unoccupied land. The claimants have gone into the State courts where they will undoubtedly be beaten, but, as they are pretty stiff-necked chaps, and have considerable money at command, the question in dispute is likely only to be determined in the court of last resort—the Supreme Court of the United States."

Even the sacred precincts of the District of Columbia have felt the squatter's power, for not many years ago—it was when Wilson was Commissioner—a citizen with the uncommon cognomen of John Smith, found in this District of Columbia, 30 or 40 acres of Government land for which he put in a claim and got a patent. The land at the time was unoccupied. It now is included within that beautiful suburban place of villas known as Le Droit Park, near the Howard University, where Col. E. C. Ford and 40 or 50 other high-toned gentlemen live and enjoy their *otium cum dignitate*.

It is, in fact, well known to the interested few in Washington, that in every thickly settled State where the Government has ever had any land to dispose of, there are omitted parcels which have never been sold, but are mostly occupied and improved, and which could be pre-empted with impunity.

The law reports are full of cases where parties have been disposed after years of occupation and improvement, yet they suffer all the consequences of carelessness in not scrutinizing the title to their possessions.

The present aspect of our land laws seems inclined to regard every man as a competent lawyer and expert searcher of records, instead of being an ordinary patriot expecting protection against land sharks. The caveat emptor idea is carried to extremes, and it is to be hoped that some future legislative body will be endowed with sufficient wisdom to prevent the abuses of confidence in land transactions and provide for the bone and sinew of the nation without compelling him to waste his substance in law suits.

New Enterprise in Nevada County.

Within the past six months or a year a great deal more interest has been manifested in the development of mines in California, than has been the case for a long time. For several years past our capitalists and mine investors have been running after mines, in other States and Territories, to the great neglect of those nearer home. This has been not only detrimental to California mining interests, but, generally speaking, to the pockets of those who overlooked mines of better worth at home to go to a distance.

In some of the older settled mining districts of the State, old abandoned mines have been

on the "bar" or "rim rock." They went through this hard formation for more than 20 feet, when they came on a ledge which in the last four feet widened from nothing to eight inches. This is in the softer character of rock. Another ledge also came in at one side and on top, and of a different character.

The ore in the eight-inch ledge looks like that from the Rocky Bar, but no drifts have yet been run, the shaft being the only development as yet. Two batches of the rock from this upper part of the shaft have been worked, and yielded \$25 and \$42.50 per ton, without the sulphurets. They have a 24 horse-power engine, hoisting works, cars, etc.

All the ledges in the vicinity of the hill on which the location was made have been rich. The famous Allison mine, the richest in Califor-

THE CALIFORNIA LILAC MOTH—*Saturnia Ceanothi*.

relocated or re-opened, and new prospecting shafts sunk and partly prospected claims judiciously worked; and in a large number of cases, the mines thus developed have proved good properties. In Nevada county this has been the case in a number of instances, and scarcely a week passes in which we do not hear of several new enterprises of this character.

The latest of these to which our attention has been called is that of the Surprise Con. G. M. Co., on the Allison Ranch, Nevada county.

nia, is 800 feet west and 100 feet below the ledge running into the hill. They are, therefore, on historic ground, with good surroundings, and it is not unreasonable to expect a good paying mine in their claim; much more so than in an undeveloped and unprospected region. They have passed through the hard rock and into the soft, there finding the ledge, and the company consider they have good prospects. The company has incorporated with a capital stock of 50,000 shares, of which 20,000, at \$1 per share, unnecessary, have been set aside for a working capital. Frank A. Hill, Manager of the Sweepstakes Flow Co. of San Leandro, from whom we obtain the facts concerning the mine, is President of the Surprise Company; S. S. Bird, of Stockton, and Patrick Dillon and John Lundy, of Grass Valley, are also Directors, and well known in this community. They are developing the Surprise ledge, and intend also developing the Hartley at the first opportunity.

Appleton's Journal quotes a calculation by

THE COCOON.

The claim adjoins the old Hartley ledge on the south, and is supposed to be an extension. The Hartley was worked in early days. The south end was first worked, and money enough taken out to build works at the other end. The shaft at the new works yielded \$30,000, but the men who were working on a ten per cent. contract quarreled, and work was given up. The works were soon afterwards burned for the second time. The Surprise comes next this claim on the south, the company having also leased the Hartley, with the privilege of purchase, at a stated price. In the Surprise the shaft was started last May, and after getting down 153 feet the ledge pinched out to nothing

LARVAE, GROWING AND MATURE.

Berthelot, the eminent French chemist, of the number of combinations which may be made of acids with certain alcohols. He says: "If you give each compound a name, and then print 100 lines on a page, and make volumes of 1,000 pages, and place a million volumes in a library, you will want 14,000 libraries to complete your catalogue."

The steamship *Gallia* arrived in New York from Liverpool, and brought \$550,000 in British gold bars and American gold coin. The *Westphalia*, from Hamburg, brought \$1,300,000 gold coin in 20-franc pieces.

A Beautiful California Moth.

EDITORS PRESS:—I send you a curious thing which I found on one of the trees on the college grounds. As I like to know all about the peculiar things I discover, I send you this for explanation.—WILLIAM BROWN, Washington College, Alameda county.

The curious thing which our young friend sends us is the cocoon of a large moth. If he is acquainted with the transformation of insects, he knows that the cocoon is made by the caterpillar just before it enters the pupa state, and that next spring, if the insect has not been injured, there will emerge from this cocoon a splendid, large moth, which will lay eggs from which caterpillars will hatch, and these caterpillars, when they have attained their full growth, will again spin cocoons and thus the succession will continue. As these large moths produce but one brood a year, the cocoon may be called the winter residence of the insect.

In order to show the transformations alluded to and at the same time to embellish our journal with engravings of one of our most magnificent California insects, we present on this page the illustrated life history of *Saturnia Ceanothi*. This moth is of the tribe of spinners (*Bombyces*), the name being derived from *bombyx*, the ancient name of the silk-worm. The genus *Saturnia* takes its name from the surname of Juo, daughter of Saturn, of ancient mythology. The specific name *Ceanothi* is borrowed from the shrub *Ceanothus*, upon which the larva feeds; it also feeds upon the *rhamnus* and rarely on the *hesperomeles*.

The *Saturnia ceanothi* is not found in the Eastern States.

Its nearest relative there is *Saturnia cecropia* or *Attacus cecropia*, as it is also termed by entomologists. The *cecropia* is also used as a silk-producing moth, and is being acclimated in France for that purpose. A recent issue of *La Nature* contains accounts of rearing this moth by A. L. Clement. The cocoons were introduced in France at the beginning of 1878 by the Acclimatization Society. To give an idea of how the entomologist loves his pets, we quote from Mr. Clement's writing as follows: "I had reared my caterpillars in the open air of my work-room, and they were now about four inches long. One could hardly take a step without crushing them; they were everywhere—in the dining-room, kitchen, parlor, bed-room, closets and even in the beds." The silk from the *cecropia* is very strong, and is expected to produce goods possessing remarkably solid qualities.

The *Saturnia ceanothi* could also be made useful for the production of silk of a heavy, coarse quality. In talking with Dr. Behr, of this city, our foremost entomologist, he expressed a desire to experiment with this silk-producing qualities of our native insect. If any of our readers who may see the cocoons like that shown in the engraving will gather them and send them to us, we will give them to Dr. Behr for experiment, and in due time report the results of his investigations.

Engineering Triumph.

The result of the jetty system of Capt. Eads in the Mississippi has been eminently successful, and the first great ocean steamship to enter the mouth of that river passed over the bar Saturday, November 1st.

The *City of Bristol*, of the Inman line, having a draft, when laden, of twenty-four feet seven inches, entered through the South Pass, and Capt. Eads, whose engineering skill has removed so many of the obstructions which commerce has encountered at the sea-gates of the Father of Waters, is not the one who will rejoice most or longest at the event. The triumph belongs most of all to New Orleans, a city which must see in the advent to her wharves of the first great ocean steamship a sure promise of that commercial importance which direct communication with European ports can not fail to yield her. And, through the hands of New Orleans, great steamships must soon bring across the ocean the wealth of foreign lands with which to make glad the vast regions beyond, and the whole Mississippi valley might well have rung with shouts of welcome as the *City of Bristol* swept through the channel from the sea. The event to which we direct attention is made especially conspicuous as an indication of that marvelous development which awaits the South.

To the Pacific coast the event is fruitful of beneficial results, and the benefits to be derived from the opening of New Orleans as an ocean port will be more apparent when its connection with San Francisco is considered. We have always understood that ocean freight was as low from New Orleans to European ports as from the Atlantic cities, and hence the odds are very much in favor of New Orleans by many hundred miles less of railroad freightage. Our mines and mineral resources will receive fresh impetus, and developments will be encouraged by the fact, that transportation can be afforded in every direction.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 202 SANSOME ST., N.E. COR. FINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

SHEET IRON PIPE.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Out, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY &
CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the
Extraction of their respective Metals without Quick-
silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.
It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.
Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including
the Chlorination Process for Gold-bearing Sulphurets,
Arsenurets, and Gold and Silver Ores generally, with
120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same etc. appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles: Smelting, Mexican process, Chilean process, Kroehke's process, etc. Under "Pulverizing Machines" are described the anstra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

UNITED STATES

Mineral Land Laws, Revised Statutes

AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 30th, 1860; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

To Mining Men.

The undersigned, by the use of a Gold and Silver Indicator, is enabled to point out and trace with accuracy lines of Gold or Silver Deposits, whether in Veins, Mines or Gravel Diggings. Can tell whether the deposit is large or small, and near the approximate value.

For information address S. W. HOWLAND,
1304 Ellis Street, San Francisco, Cal.

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET.
Near First and Market Streets.

Ores worked by any process.
Ores sampled.
ASSAYING in all its branches.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is hoisted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular. We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

Mines and Works of Almaden.

Translated from "Annales des Mines" BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 60 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

CONTINUED FROM PAGE 309.

Deidshelm, the Superintendent, and was shown some specimens. He says: The formation is certainly a promising one. The crosscut is six ft in this ore. The ore contains black sulphurates and chlorides, with spots of stannite. The outside of the specimen secured is covered with fine rich chlorides, and much of the ore seen in the paper is fine soft chlorides. There is no hesitancy in saying that the whole as shown would mill \$100 per ton, while selections could be made which would go high in the hundreds. The situation on Wednesday showed the face of the cut still in the ore vein. The crosscut on the 2200 level is being prospected by the diamond drill as a precaution against water. Its total length is 24 ft.

MEXICO.—The north drift, 2300 level, has been extended from the Ophir incline into Mexican ground, and will be continued on to intersect with the joint Union winzes on this level. It is now in a very favorable vein formation, carrying low-grade ore, and a similar, if not the same, formation has been encountered in this joint Ophir crosscut west on this level.

SHERA NEVADA.—The workings both north and east from the bottom of the east shaft are abandoned on account of water, as the mine has all that it can possibly handle with the amount of compressed air at command, and both drifts are secured. All is being done to open up the 2400 station of the incline that can be, and the work is progressing well.

CON. VIRGINIA.—There remain some 200 ft yet to be made between the south drift, 2150 level, and the north on the same level in the foot of the joint Best & Belcher winze from the 1900 level.

PICOCHE DISTRICT.

RAYMOND & ELY.—Record, Nov. 8: Everything looks well on 1000 level; things look well and plenty of low-grade ore. Mill started up yesterday. Mr. Kilburn is progressing very well in grading and getting ready to put roaster in position when it arrives and has many men to work; have plenty of black ore on hand when furnace starts; have on hand now about 400 tons of ore here and at mill; 8th and 9th levels look well and promising; on 11th future prospect very encouraging.

HILLBURN.—The present working well and taking out its 50 tons of ore daily. The stopes producing their usual quantity of ore. This vein in the intermediate drift at extreme east, fourth level, continues good and the ore gaining in lead. The west ore body on fifth level still holding its own, the two winzes being sunk on it still showing the same character of ore and giving average assays. The upraise drift above the central ore chamber has been run some 60 ft, continuing in the same quality of ore.

MAYFLOWER.—The Superintendent says: Commenced drifting west in the ore in bottom of winze at a depth of 114 ft; total depth from surface, 244 ft. Have extended drift 11 ft since November 1st. The ore encloses the whole drift; no lime in sight. Shall push this drift for 40 ft, then crosscut both winzes, to find out the extent of the ore body. As the drift is being pushed forward this ore continues to improve in quality.

PARADISE DISTRICT.

RICH ORE.—The Silver State of Winnemucca says: Charles Kemler brought a piece of ore from the new discovery of Graves and Nace, in the Paradise mountains, some six miles west of the village, to this office to-day. It is one of the finest specimens of ore we have yet seen from the Paradise mines. The ledge, from the croppings of which it was taken, is four ft wide, and the ore assays from \$200 to \$2,000 per ton. Mr. Kemler sends the specimen to Charles Forman, a prominent mining man of Storey county, this afternoon.

WILLOW CREEK DISTRICT.

PROSPECTING.—Silver State, Nov. 8: There is considerable activity among prospectors on Willow creek, not far from McCollie's station, on the Idaho road. Very rich silver-bearing quartz has been found on the surface of the ground, and prospecting is being done. The ledge from which it floated. The late mining discoveries on the east or Paradise side of the range, which divides Paradise valley from Willow creek, encouraged prospecting on the west side, where very rich float rock has been found. There are evidences of rich mines on both sides of the mountain which bounds Paradise valley on the west, and rich strikes are liable to be made there any day.

SANTA FE DISTRICT.

RICH DISCOVERY IN ESERALDA COUNTY.—The Reno Gazette of the 10th inst contains the following from its own correspondent: "A very rich discovery was made a few days ago by a prospector named Wm. J. Morris. The ore is a black sulphurated iron ore, and the assay was taken from the surface, and several assays were made ranging from \$2,200 to \$2,926. The vein is 22 inches wide, and in a limestone formation. It is pronounced by old prospectors to be the greatest discovery ever known. Work will be commenced on it immediately. It is about five miles from the famous Sunrise mine, in a northern direction."

ARIZONA.

CONTENTION MINE.—The Citizen says there is a report in Tucson just from Tombstone that a marvelously rich strike has recently been made in the Contention mine, the ore assaying about \$900 in gold and up in thousands in silver. By some this report is thought to be based on the fact that some two weeks ago a strike was made that Mr. Dean said would, if on the Comstock, add a million dollars to the value of the mine.

A NEW DISCOVERY.—Mr. James Lee and others discovered a ledge of mineral some eight days ago, situated about 40 miles from Tucson in the Santa Catalina mountains. An assay was made of an ordinary piece of surface ore which gave a result of \$20.43 in silver and \$201.50 in gold. A choice piece gave an assay of \$1,300.

ITEMS.—The Herald says: Sam Hill, returned from Tombstone last week, brought 20 pounds of ore from the Zulu ledge, which he had Blake & Co. assay, and the result shows \$314 silver and \$97.80 gold. The ledge is between four and five ft wide. Mining news from Mohave county is encouraging. The editors of the McCracken company will run the mill until they get their money, after which the company will run it themselves. The Signal mill is running steadily.

ANCIENT MINING TOWN.—The Sentinel publishes the report of the finding, at Tucson, of a mining town in Papago country, southwest of Tucson, not heretofore known to the whites. It created much talk, and it is thought that rich mines are near there.

COLORADO.

ITEMS.—Georgetown Courier, Nov. 6: Ore from the Tilden lode runs from 100 to 1,000 ounces. The Mammoth mine, Sherman mountain, is being worked by Chas. H. Loring, lessee, who is working on a vein of galena ore from three to six inches thick, that mills about 40 ounces in silver, and 50% less in gold. The ore is shipped to Bond's smelting works, at Boulder. The lessees of the Magnet mine, on Saxon mountain, are stopping and raising on a vein of ore about six inches thick, which is worth about 400 ounces per ton. Vaughn & Co. are drifting and stopping in the upper level, on from one to two inches of ore that mills from 500 to 600 ounces.

PAY ROCK MINE.—The North Branch, a vein of ore which branches from the North vein, is in excellent pay at the Pay Rock tunnel level, the Silverbank tunnel level and at the first level, 85 ft below the latter, making a distance of 172 ft perpendicular which contains good pay, and at each of the places where it is worked the ore is of a uniform grade, milling from 700 to 800 ounces per ton. The best pay at present on this vein is at the Silverbank tunnel level, where the vein is from six to eight inches thick and solid. On the 1st level the vein was intersected by a crosscut 50 ft long, which was run from the north vein at a point 30 ft east of the tunnel—at this point the crosscut has not yet reached the north wall of the lode. At the point where intersected the lode shows six ft of ore with stringers of ore scattered through it and three veins of solid ore ranging from one to two inches in thickness. A drift will soon be started as intersected, both east and west, as the indications point to a large body of ore not far from the head of the crosscut.

IDAHO.

COAL DISCOVERY.—Statesman, Nov. 4: We have it from parties every way reliable, but who are unwilling that anything definite shall be made public yet, that a large and valuable vein of coal has been discovered in the vicinity of Boise City. At a depth of 10 ft on the vein, the coal is very nearly pure and of the kind known as semibituminous.

MONTANA.

PENOBSCOT MINE.—A writer in the Butte Weekly Miner of the 4th inst. says of this mine: The ore vein at the bottom of the shaft is nine ft wide. Stopping has been done on some of the upper levels, but most of the ore is lying on the stulls awaiting to be hoisted to the surface. Several hundred tons of broken ore are lying in the drifts. About 400 ft west of the main shaft a short crosscut taps the vein; from this point a drift has been run west 330 ft, tapping the bottom of the old Snowdrift shaft, or discarding a great deal of the Penobscot and Snowdrift lodes. A little east of the bottom of the old Snowdrift shaft a winze was sunk 90 ft and some very rich ore found, almost equaling the famous bonanza which first brought the mine into such notice two years ago. On this level a vein was found running north and south, or at right angles to the Penobscot. A drift has been run on this lode 100 ft; a good vein of ore three and a half ft wide was found all the way. The spurs running off from the vein show to a practical miner that the Penobscot is a true fissure. One thing is noticeable, that the farther away from the rich surface pocket the workings are the less base the ore is, and the higher percentages of the noble metal can be saved. Only a small streak of the black or carbonate ore is found in the deepest working, the rest of the quartz being nearly white and quite free from any base metals.

NEW MEXICO.

GENERAL ITEMS.—A correspondent in the Grant County Herald writes of the mines at Georgetown: There is a great deal of very good ore coming out of our mines just now. The McGregor mine alone has about 100 tons of \$200-ore on the dump, ready for the mill. Alexander and Malcolm McGregor have just sent down to the Mimbres M. & R. W. about 30 tons, which they think will mill near 200 ounces per ton. The ore are very free and generally high grade. The McNulty mine has recently been turning out considerable ore, under the superintendence of Col. Ledbetter. It has porphyry wall running its whole length, and is supposed to be a true fissure vein, just as the Nalad Queen, which is an extension of the same mine, is now showing itself to be. Messrs. Meredith and Ailman are sinking in the Nalad Queen, and at a depth of more than 200 ft from the surface, have a vein of very rich ore, over two ft wide, going down along the lower side of the wall, besides several rich streaks, pockets and feeders at various parts of the mine. There are now in store about 20 tons of first-class ore which will run 50 cents per lb. More than enough second-class ore is taken out daily to run the mill. The Satisfaction mine has been turning out considerable ore of late, a large amount of which has been sent to the Lone Mountain mill for reduction. Some of this was low grade, other of very good quality. Our mills have been crowded to their utmost capacity for months past, and still we have 300 tons of ore now in waiting to be reduced. We need more milling capacity very badly.

Recent Decisions by the Commissioner of Patents.

Process of Making Drop Shot-Ex parte Wintherlich et al.

Decided August 26th, 1879. Interlocutory appeal from the Primary Examiner.

1. A machine and its product cannot be joined in one application when they constitute different inventions; but when, being inseparable in their nature, they constitute one and the same invention, they may be so joined.

2. The applicant cannot be required to suggest considerations or proofs which shall establish these relations between the machine and the product beyond the possibility of reasonable doubt. It is enough if the reasons on which he bases his claim that the two are inseparable, overbalance the opposing reasons in the judgment of the tribunals having jurisdiction of the case.

3. These reasons may be suggested by the laws of nature or by the testimony of witnesses. In cases of evident conflict between the two the former must, of course, prevail.

The decision of the Primary Examiner is affirmed.

Manufacture of Rakes-Ex parte Carter.

Decided August 26th, 1879. Interlocutory appeal from the Primary Examiner.

1. In an application for a process patent, every stage or sub-process distinctly claimed, which is capable of illustration by drawing, must be illustrated; but it is not, in general, necessary to illustrate by drawings the several steps in each stage of a sub-process claimed.

2. Where the applicant claims as a single sub-process, the bending of a rake and the finishing of the shoulder at the junction of the shank and rake-head, it is not necessary for him to illustrate by drawing the blanks with the shank bent, but not compressed or finished about the head.

3. If a drawing of dies used in a sub-process can fairly be regarded as essential to such a description of the sub-process as will enable those skilled in the art to practice the invention, then a drawing must be furnished, although novelty in the construction of the dies may not be claimed.

The decision of the Primary Examiner on both these points is overruled.

Knit Fabrics-Ex parte Chase.

Decided August 26th, 1879. Interlocutory appeal from the Primary Examiner.

A drawing is required by Rule 18 and by Section 4889 of the Revised Statutes when the nature of the case admits of it; and a claim for an article of manufacture must be accompanied by a drawing of the article, whether such drawing be or be not necessary or useful in the examination of the case.

The decision of the Primary Examiner is affirmed.

Actiengesellschaft Apollinaris-brunnen vs. Saratoga Seltzer Spring Company.

Decided August 26th, 1879. Appeal from the Examiner of Interferences.

Motion to re-open interference.

1. The effect of Sections 1750 and 4905 of the

Revised Statutes is to authorize the Commissioner of Patents to establish rules for taking depositions before United States Consuls in foreign countries. There is no authority for taking depositions in interference cases. These statutory provisions do not excuse themselves, nor provide for their own execution otherwise than through rules to be established by the Commissioner.

2. The rules for taking depositions in interference cases, now in force, do not apply to foreign countries.

The decision of the Examiner of Interferences is affirmed.

U. S. Circuit Court, Northern District of New York.

Garretson vs. Clark, et al.

Decided September 3d, 1879.

1. Where the entire value of the whole machine as a marketable article is properly and legally attributable to the patented features, the profits may be estimated by showing the profit derived from making and selling the articles containing the patented features, and the profits realized from the manufacture and sale of other forms of the same article not embodying the patented features.

2. The burden is on the plaintiff to lay a basis by evidence for ascertaining the proper profits or damages, and it is not the province of the master nor of the court to suggest any specific line of proof as proper or necessary.

The prayer of this petition for a rehearing is denied with costs.

U. S. Circuit Court, Northern District of New York.

News in Brief.

The Indians at Williams Lake, B. C., are said to be starving, and their chief has published a pathetic letter in their behalf.

The Treasury Department the other day purchased 530,000 ounces of silver for the Philadelphia and San Francisco Mints.

The attempt to raise the German ironclad Grosser Kurfürst, sunk in the British Channel, has been postponed until the 24th inst.

The Arizona troops who recently pursued Victoria's Apaches in Mexico have returned, having driven the savages 60 miles from the border.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

VALVE MECHANISM FOR DIRECT ACTING ENGINES.—Geo. E. Dow, S. F. Patented November 4th. The object of this invention is, first, to provide means for a better distribution of steam to the engine, to facilitate the motion of the piston, combined with a more economical use of the steam, and to apply particularly to the better control of engines having heavy reciprocating parts, thus making the change of stroke easier, yet bringing the piston closely to the cylinder-heads under all conditions, while thumping would be impossible. Second, in order to successfully accomplish the above the main valves of the engine must be moved by and under the immediate control of the main piston from a point somewhat later than the half-stroke. This device must have the elements of first equalizing the pressure by opening a communication between the two ends of the supplementary piston (the same being required to move the valves the latter part of its stroke), then to move the main valve by a positive movement, at first very slowly; but its motion must accelerate rapidly as the main piston approaches the end of its stroke, to the extent of opening rapidly in advance of the piston at a speed equal to or in excess of that of the main piston. Third, that an auxiliary valve must be connected to this mechanism to act the part of opening a communication between the two ends of the supplementary piston just before the action of moving to close the main valve; also, to admit steam to that end of the supplementary piston toward which the main piston is moving, just before the main valve has reached its lapped position or center of travel, and at the same time open a passage from the opposite end to the exhaust. This determines the length of the stroke, and reverses the engine by completing the latter half-stroke of main valve by steam from the steam-chest, though this movement of reversing may be accomplished in part or wholly by the engine itself at any speed in excess of that dependent upon the auxiliary valve for reversing.

FASTENING LASHES TO WHIPS.—John J. Fowler, Ukiah, Cal. Patent No. 221,226. Dated, Nov. 4th, 1879. Whip-lashes are usually secured to the stocks by means of a loop on the end of the lash and one on the end of the stock. The loop on the end of the stock is generally lashed on with waxed thread or twine, and very frequently slips off. It is a troublesome job to secure the loop to the smooth end of the stock, so that it will remain securely, and when it comes off, as it often does, must be replaced before the stock can be again used. This invention is designed to secure this loop to which the lash is fastened firmly to the whip-stock, and have it at the same time easily removable in case it should break. The improvement consists in slipping over the loop on the end of the stock a clamp with a threaded exterior, over which screws a thimble which presses the split parts together against the tapering end of the whip-stock, so as to firmly secure the loop to which the whip-lash is fastened. In this way the loop may be securely fastened to whip-stocks so that there is no danger of losing lashes by the loop slipping off.

AMALGAMATORS.—Aurslius T. Ladd, S. F. Patent No. 220,978. Dated, Oct. 28th, 1879. This invention relates to certain improvements in that class of amalgamators in which the ore is forced through a bath of mercury in a bowl or tank; and the improvement consists in pipes perforated on one side and placed in the bowl in such a position that water injected through the perforations will spread and break up the lump of ore and prevent it from packing or settling. The water which is thus admitted to the bowl dispenses with the necessity of the use of stirrers, and keeps the pulp in such a state that the particles of quicksilver and gold can readily settle, while the tailings pass off freely over the edge of the bowl and are carried away by an encircling inclosed trough.

HINGE FOR DOUBLE DOORS.—Joseph Decombe, S. F. Patent No. 220,965. Dated Oct. 28th, 1879. This invention relates to certain improvements in hinges, which are especially applicable to double doors; and it consists in a peculiar and novel construction in which two leaves of the hinge, one for each of the two doors, are supported upon the same hinge-pin, the latter being projected out from the point at which the hinge is secured the thickness of the doors, thus enabling the doors to be hung so that this post is reduced to a minimum, and is entirely concealed from the front when the doors are closed. When opened only the thickness of the two doors as they stand front to front will be exposed.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

AURORA M. Co.—Object: To operate in Placer county. Capital, \$270,000. Directors—H. C. Ladd, George L. Ladd, F. Conklin, J. C. Dessensary of San Francisco, and E. G. Spencer of Iowa Hill.

FRESNO RAISIN & FRUIT Co.—Object: To cure and preserve fruits and vegetables. Capital, \$250,000. Directors—A. J. Ralston, Josiah Belden, Oliver Holden, S. A. Miller and N. K. Masten.

CENTRAL GARDENS ASSOCIATION.—Object: To acquire lands for places of amusement. Capital, \$500,000. Directors—R. T. Van Norden, T. W. Hinchman, S. Solomons, P. B. Nagle, P. H. Blake, H. Casebolt, John Doyle, Milo Hadley and M. M. Cook.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together. sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Porcelain Sheet Metals of every description. I would call special attention to my SLOT OUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extend from abroad and will be glad in giving this place an early call. Orders solicited and promptly attended to.
32 Fremont Street, San Francisco.

Books for Miners and Millmen

KUSTEL'S ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated, 142 pages, 1870. A valuable and carefully written work. Postpaid, \$2.50. Published and sold by Dewey & Co., S. F.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with 120 lithographic diagrams, 1867. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 672 pages and 33 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Post-paid, \$10.50. Sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated, 114 pages, 1876. A useful and practical work, free from technicalities and extremely serviceable for miners use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

COPPE'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Post-paid, \$1.00. Sold by Dewey & Co., S. F.

PALACE RESTAURANT

Mining Machinery Depot,
PARKE & LACY,

NO. 7 IMPROVED

AIR COMPRESSOR.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz: that of a simple, cheap Rifle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Rifle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Rifle is such that there is a strong, unobstructed up-per-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous rifles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Rifle, and who will receive and attend to all orders.

VOLUME XXXIX
Number 21.

A Heavy Mining Blast.

On Saturday the 8th inst., one of the largest and most successful blasts ever put off in this State was fired at the well-known Dardanelles gravel mine, near Forest Hill in Placer county. About 500,000 cubic yards of hard cement gravel was moved and thoroughly disintegrated by 36,000 pounds of Judson powder. This amount of Judson powder is equal to about 2,900 kegs of common blasting powder. Five drifts with 14 Te, with a total length of 1,200 feet, were run in the face of the bank, which was about 1,000 feet long.

On Friday morning about 40 men began the work of loading and tamping, which was continued without cessation until it was completed, at 10 o'clock on Saturday morning. The powder was put in lots of from 1,000 to 1,500 pounds in 50-pound boxes in 28 different chambers, in each of which was placed three exploders, and each of these was connected by an insulated copper wire with the main wires on the outside of the drifts. These were well tamped with large quantities of clay and boulders. From the mouth of each drift and connected with the wires from the exploders, were run two copper wires to a large electro-magnetic battery, placed on a slight eminence at the right and about 200 feet from the face of the bank.

By ten o'clock on Saturday morning the tamping was all finished. A large number of people had gathered from the neighboring towns of Forest Hill, Todd's Valley and Yankes Jims and the adjacent mines, and were stationed on surrounding eminences at more or less respectful distances from the hidden power. At a quarter past ten o'clock the connections had been made with the batteries. Mr. Wm. McGillivray, the assistant Superintendent, gave a signal that all was ready, turned the crank of the powerful battery, and instantaneously the whole mass of 500,000 cubic yards of cemented gravel seemed to spring into life.

The upper and back part of the mass was thrown upward four or five feet, and the bottom thrown out and forward, and the whole mass came down and spread out loosely, over any part of which one could easily walk. Before the blast the banks stood perpendicular 175 feet. A dense cloud of dust rose from the surface and was soon carried away by the wind.

The jar was felt as strongly as an ordinary earthquake in Forest Hill and Todd's Valley, a mile and a half distant. When we consider that each pound of powder is able to move 14 cubic yards of earth the result seems almost startling.

Two more smaller blasts will be fired in a few days in the same mine. The Dardanelles is now well fitted up for work, and the recent rains will probably fill the Miners' ditch, of some 3,500 inches capacity, and owned by the Dardanelles company, and there is little doubt, with the very rich prospects in the ground to be worked, that they will make some fine cleanups of bullion during the coming season.

EXPLOSION IN A RAILROAD TUNNEL.—A terrible explosion took place in Tunnel No. 3, near Wright's station, on the South Pacific Coast Railroad, on Wednesday morning, by which 24 Chinamen were instantly killed, and a number of others injured. The cause of the explosion is supposed to have been the ignition of petroleum gases.

THE COLORED people's first industrial exposition opened at Raleigh, N. C., Nov. 17th, with flattering prospects.

GREAT excitement exists in Spain over the renewed insurrection in Cuba, which has assumed an alarming aspect.

THE Nihilist trials have begun at St. Petersburg before a court-martial.

Where to Explore for Minerals.

While it is quite certain that the mine prospector is pretty well acquainted with the geological formation of the region where the precious metals may be looked for, yet those mineral formations which have once been conformable to rules may have become so modified and disguised by volcanic action that original features cannot be recognized, and hence the liability to overlook a rich deposit or excellent vein becomes more common as the divergence from fixed and uniform laws of structure and formation become more varied.

There is one important fact which experience seems to have demonstrated, which is, that the system of fissure veins of extensive and profitable mining districts have been discovered and worked in comparative proximity to the junction of the primitive with the secondary formations, sometimes in the former, sometimes in the latter, and frequently in both strata. Gold and silver, while conforming to this position,

erecting expensive works before proving the mines.

This day is not far distant when the notion of exploring waste places shall be forgotten, and when mining shall have become the precursor of milling, that the quartz veins of California will be worked as economically as those of Brazil, Australia and New Zealand. The hundreds of ledges now lying unvalued and idle, will be profitably worked, and rich discoveries follow the exploration of these low-grade ore ledges, which are, so to speak, the finger-marks of richer ore. This region has not yet been fully explored. Its capacity as a gold-producer is well known, its indications, geologically speaking, are certain. Silver is easily attainable, gold is the *sine qua non* of the world's market, and exists in our midst in quantities sufficient to remove all fear of any future diminution in the supply. Hence here is the spot which should excite the explorer's energies. Nearly one-half of the entire gold production of the country comes from California. Silver is increasing in quantity, and now exceeds the supply of gold. The proper balance can be preserved by devoting more time to the exploration for gold, and to the solution of the problem of working low-grade ore to advantage. The

A Gas Engine.

We illustrate herewith the Otto Silent Gas engine, a machine which furnishes power by means of successive explosions of common burning gas in the cylinder, thus dispensing with steam, boiler and all the attendant nuisances of the common form of engines. An examination of this engine, which may be seen at H. P. Gregory & Co.'s, shows it to consist mainly of a jacketed cylinder, with piston, slide valve, and governor having a cut-off mechanism to regulate the supply of gas according to the varying load on the engine. The pressure utilized for the production of the power is generated in the cylinder and at once availed of therein to propel the piston. This pressure is due to the combustion of a peculiar mixture of common coal gas, which is ignited by a small flame carried from a burning gas jet outside into the cylinder by the motion of the slide. The principle of combustion in this gas engine is entirely new; a small part only of the charge is combustible, which, on ignition, serves to expand the remainder, thus avoiding shock, and effecting—when compared with other motors of this class—a vast economy. The Otto Gas engine possesses the least number of working parts, and the greatest simplicity of mechanism yet attained in a gas engine. It runs with an extreme smoothness and regularity of speed. The gas engine, requiring no boiler, avoids all the expensive attendance or loss of time, which the watching of water level, feed pump and steam-pressures gauge demand in a steam engine. The gas flows in freely, and there is no handling of fuel of any kind, and no ashes. Thereby, hardly any item of cost for attendances is to be considered; almost the total expense of running is for the gas alone. The quantity required has, in the Otto engine, been reduced to about one-fourth of what older constructions required, and will average for the different sizes of engines, 21½ cubic feet of gas per inch H. P. per hour. While running, however, the cut-off being in constant operation, the "gas consumption is limited in proportion to the load on engine." Thereby, in practice, in many cases only one-third or one-half of above rates of consumption is reached. The engine costs nothing while standing, and is started and stopped without waste of fuel and time. Another important pecuniary saving is often to be derived from low rates of insurance.

THE NEW OTTO SILENT GAS ENGINE.

appear to require the additional assistance of a partial disturbance, the same power operating to lessen the previous deposits of the volatile base minerals by dispersion. Phillips says, in his "Explorers' Companion," that he has never seen a profitable mine for either lead, antimony, zinc, mercury, or the other very fusible and volatile minerals, within the distance of two miles from any primitive range, but with very few exceptions they are found ranging from this distance to some few miles away. Very small patches of primitive rock, accompanied by the appropriate surrounding conditions, have produced some very extensive ramifications of rich veins, so that very large primitive mountains need not be always present, or comparative mole-hills be despised; for where these latter arise in the congeal clay slates, or in metalliferous carbonates of lime and magnesia, the prospects would be good.

The western slope of the Sierra Nevada is so well situated for climate and proximity to the ocean, and so amply supplied with wood and general provisions, that it will undoubtedly become the most profitable as it is now the most interesting and extensive mining field in the world. The immense deposits of precious minerals are practically inexhaustible. The vast ore veins which are either remaining unexplored or unworked by reason of their low-grade quality, will in the future demand, as they deserve, greater attention as nature's principal and solid storehouses. There has been unsystematic mining, but the experience of the past has demonstrated beyond a peradventure the futility of

field is here, the means, however, are yet undetermined; and, as a general thing, exploration remain in many localities *in statu quo*, under the impression that there is nothing more worth working for, whereas the truth is that the rich harvest has hardly begun to be gathered.

A SINGULAR FACT.—Judging from the accounts of gold deposits in Eastern and Southern States, it is quite strange that the precious metal is not dug out. The local papers glow with the richness which exists in the soil, and the Rocky mountain and Pacific slope mines fade into insignificance when compared with the treasure awaiting a resurrection, perhaps. Here is what the *Alabama Times*, of Columbus, says: California and other Pacific States have so long kept the eyes of the gold-hunting world in that direction that the rich veins of the precious metal which run in broad and inexhaustible lines through Alabama have almost been lost sight of. We have often been told by old Californians that with the same machinery and effort, more gold could be taken from the Tallapoosa mines than from many of the most popular ones on the Pacific coast. In former years we knew something of the gold veins of Tallapoosa, especially of those about the once famous Log Pit mine, and can say that they, unskillfully worked, yielded many thousand dollars worth of gold.

FOOTPRINTS OF VANISHED RACES.—Under the above title, Chancy R. Barns, 215 Pine street, St. Louis, Mo., has published an attractive volume, of which A. J. Conant, A. M., is the author. The work refers to the Mississippi valley, and comprehensively treats of the antiquities of the vanished races that once dwelt upon this continent. The preface, giving the results of three score years of investigation into the antiquities of North America, says: "Notwithstanding all this labor and study, the great questions continually repeated, which were suggested when our antiquities were first noticed, still remain unanswered, namely: (Who were the authors of these works? What was their origin, and what were the causes of their disappearance? Were they the redmen found in possession of the continent at the time of its discovery?" The author holds to the opinion that the redmen were not the authors of the most extensive works, and regards the ware of prehistoric America superior to those of Europe. The volume is very interesting throughout, and collates all the facts and researches that have been made in this study, presenting new and well-grounded ideas. The work is of general interest, and treats its subjects in an extremely pleasing and readable style.

PRESIDENT HAYES is visiting New York city.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Nevada Mines.—Esmeralda County.

EDITORS PRESS:—In my travels through the State of Nevada I was surprised to find so many large mines without milling facilities, and I will give you the particulars of the Victor mine, situated at Candelara, Esmeralda county. This property has been so thoroughly prospected as to place it among the best mines of the State. In the past four years there has been expended \$100,000 in its development, and have opened a fine body of ore in all the shafts and tunnels. One main tunnel of 700 feet cuts the ledges at right angles, and gives a vertical depth for stoping of 600 feet, with lateral drifts of 800 feet more, exposing a body of rich ore that, from calculation by measurement, reaches the enormous aggregate of 200,000 tons, the average of which, by mill test, was over \$50. About 3,000 tons has been hauled a distance of 26 miles to the New Boston mill, and worked with the above result, without roasting, and this has been a fair average of the whole, while much of it would go above that figure under a more economical mode of working, as the assays show a much higher percentage of the precious metals, silver predominating. The silver exists as a chloride in combination with sulphur and antimony; is very easily roasted and worked by the use of salt, of which there is a great abundance in the immediate neighborhood that can be had for a few dollars per ton. Shafts have been sunk on the various ledges, 500 feet in depth, connecting with the lateral drifts, making perfect circulation. These shafts are sunk on the ledge, showing a continuous ore body from the surface to the tunnel. The ledge at the surface shows a width of four to six feet, and increases as depth is reached. In the tunnel I found it from twelve to twenty feet wide.

The ledges are true fissure veins, with foot and hanging rocks, the country rock being elate and porphyry; the direction of the veins running east and west, the range of mountains shows no volcanic disturbance after the upheaval, which insures permanency in the ledges.

The amount of ore on the dumps, as near as could be measured, is about 10,000 tons, which is presumed will mill above \$50 per ton, as that is the average of what was milled at Marietta and New Boston. The three claims covered by the surveys and claims, viz., the Victor, the Magnet, and the Chloride, gives ample territory to work for many years.

The claims lie side by side or nearly so, the Victor extending 400 feet to the east of the other two; the size of each being: The Victor, 1,400x300; the Chloride, 1,000x300; and the Magnet, 1,000x300—giving a width of 900 feet and covering all the ledges that crop out on the surface. The three locations having been made on separate ledges, each of which has been prospected and opened by tunnels and shafts, the amount of development and the quantity of ore in sight makes it one of the most promising properties ever developed. The ledges crop out the entire length of the claims, and are a continuation of the celebrated Northern Belle mine that has paid such large dividends for years; and as there are three claims embraced in this property, it makes it far more valuable than the Northern Belle.

The whole may be summed up in the following particulars: Length of tunneling, 1,800 feet; total feet of shafts, 900; amount of ore exposed in tunnels and shafts, 200,000 tons; amount of ore on dump at time of examination, 10,000 tons.

The improvements on the property at mouth of tunnel consist of one boarding-house sufficiently commodious to accommodate 50 hands, blacksmith shop with complete outfit, and stable for several head of horses.

Considerable of the ore will mill several hundred dollars per ton, but will average about \$50. The facilities for mining could not be better, as the ore can all be taken out through tunnels to a depth 1,200 feet, thus avoiding the necessity of hoisting works.

Wood is abundant in the adjacent mountains, and can be delivered at the mine for \$10 per cord. The water will have to be brought a distance of 10 miles in pipes, but any quantity can be had from the springs where it is intended to be tapped. The cost will not exceed \$20,000, and can be made a source of revenue to the company of \$25,000 per annum, as all the water used there now is hauled a distance of 10 miles in wagons, and sells for five cents per gallon. The town of Candelara has a population of about 2,000, and will be largely increased as soon as the water is brought to it.

The weather is pleasant the whole year, or sufficiently so to be able to work outdoors nearly every day. The property is about 100 miles from the C. P. R. R., leaving it at Wadsworth, and a narrow-gauge railroad is in contemplation that will be built within the next year, which will bring this property much nearer to the center of business. In fact, with railroad communication it would be one of the finest properties in the country, as there are millions of tons of fine ore lying there waiting to be converted into bullion. If this property

was properly laid before capitalists, there would be no difficulty in getting the amount necessary to erect machinery and bring water to the mine, for it will return the investment many hundred fold. There are many other developed properties throughout that country worthy of mention that I will speak of hereafter. The mill at New Boston some 18 miles away, where the Victor ore was milled, is now putting in an improved roasting furnace, and as soon as ready will start up again on this ore, when they expect to find the ore to return a much larger yield than when worked raw, as much of the chlorides were lost with the slums that ran away in the tailings.

I will give you some particulars of the mines in the vicinity of New Boston in my next, as they are worthy not only of a notice in the columns of your paper, but also the attention of capitalists.

S. F., Cal., Nov., 1879.

Coos Bay.

[Written for the Press by F. F. V.]

Coos Bay is an inlet with a mouth like that of a river, and ramifies in many directions, forming narrow sloughs, or bayous, up which tide-water forces itself, making navigation very much dependent upon it. The bar is troublesome and dangerous in the stormy season, needing to be "improved" by the expenditure of money enough to build jetties that would confine the channel between fixed limits, compelling the water to keep the entrance clear. The resources of the country about the bay are sufficient to warrant the appropriation by Government of such a sum, and undoubtedly the day will soon arrive when this work will be commenced.

There is a marked similarity between Coos Bay and the general features of Puget sound, the difference being chiefly in the dimensions. As the Umpqua river is a smaller copy of the Columbia, so Coos Bay is a diminished Puget sound, the wooded shores, the numerous arms and the milling of lumber appearing to reproduce the same effects. So heavily timbered is the country adjacent to its waters that cultivation of the earth is but little carried on, even vegetables and fruits being scarce, while the climate and the soil are favorable enough for their production. This negligence on the part of the settlers sometimes conspires with rough weather on the bar to produce a stringency in the provision market. Last winter, for instance, there were 72 consecutive days when vessels could not come in or go out, and during this period many persons were forced to live on very simple rations, if not on short allowance. It is at such a time as this that railroad projects are discussed with greatest earnestness, and when the people desire something more than a political relation with Oregon.

Coming in from the sea, Empire City is the first town arrived at, and is about three miles inside the bar. It is built on a bench of land, with an incline towards the water's edge below it, and with timbered bluffs extending along the bay above and below it, or, as the hay lies, north and south of it. Opposite to it is a long line of sand hills, forming a barrier against the sea, which from the "lookout" on the bluff is plainly visible. Empire City was founded about the same time with Gardiner and Scottsburg; indeed, all the towns in this region appear to have been started about the same period, from 1850 to 1854. It is a port of entry; is the county seat of Coos; has a shipyard, a large steam lumbering mill, and a considerable trade in general merchandise.

From Empire, one of several small swift steamers conveys us up the bay to North Bend, a distance of two or three miles. This place is entirely a lumbering and shipbuilding point, and is owned by the Simpson brothers. It has a pretty site, is neatly built, has neither hotel nor saloon, but contains within itself all the essentials for the comfort of its people, employers and employed. The mill has a capacity of 28,000 feet per diem. At this shipyard was built the beautiful, full-rigged ship, *Western Shore*. The fine vessel, the *Tam O'Shanter*, was also built at this place. The elegant finishing of these vessels is due in part to the beauty of the cabinet woods of this region, especially of the myrtle, which for color and fineness of grain is not surpassed in beauty by any wood in the world. North Bend has rendered itself famous, and done Oregon good service in sending forth vessels of this class to advertise her resources to the world, as well as the talent and enterprise of her shipbuilders.

A short distance above North Bend, at the head of the bay proper, is Marshfield, the principal town on these waters. It reminds one of Astoria, being situated on a hillside, and having a considerable portion of its business houses built upon piling or "made ground." What its population is it would be difficult to guess—probably about 600. It has good hotels, several stores of general merchandise, and the usual supply of special shops, that make a considerable show of trade; extensive wharves and warehouse, and a general appearance of prosperity. Lumbering is the chief business carried on here, which together with shipbuilding employs in ordinary seasons a large number of men. The present season, however, is less active than any former one for a long time, though the mill of Dean, Wilcox & Merchant is

running on full time, its capacity being 40,000 feet per day.

All about Coos Bay on Coos river and the several sloughs are so-called towns; but really they are only small clusters of tenements erected at different points where some enterprise has been undertaken, generally where a coal bank has been discovered and prospected. Where these enterprises have been prosperous, the usual local improvements have been made, and there are schools and stores. But excepting at Newport and Eastport there is almost nothing being done at present in the coal interest. The mines at Henryville, where a large amount of money has been invested, have proven a failure, and the costly works are abandoned. Some coal is being taken out at the Isthmus coal mine, and vessels go to Uter City to load; but the business has so declined that Uter City is almost wholly deserted, and its cottages are empty, while its ample hotel is almost without a guest.

This condition of affairs at Coos Bay is greatly the result of the transient habit of the people on this coast, which affects business everywhere. If there is a rumor that something is doing or may be done at a certain point, everybody rushes to that point. Often they are disappointed and fly with just as little reason to some other point. The people do not adopt the country and determine to make the best of it, but endeavor to drain it as rapidly as possible and get away from it. Business, which has been depressed everywhere alike, will revive by and by, and all the sooner if people instead of floating about the country will stay where they are and do the best they can under the circumstances until the tide turns. At least that is the way it looks to a casual observer like myself.

Coquille City, though on the Coquille river, belongs to the Coos Bay country, and is a promising new town, in a pretty valley, with a navigable river of its own. The inhabitants with commendable enterprise are endeavoring to build jetties at the mouth of the river to keep open the channel and insure navigation. This is done by private subscription and with money raised by entertainments, including a grand Fourth of July celebration, and will I hope prove a permanent good to the country. Efforts of this kind that show the people have come to stay and "mean business," are the results that in time will win the recognition and success that will repay those investing in the work.

Como Lode, Nevada.

The above lode, located in Palmyra district, was referred to in a letter from William Rose to the PRESS, published in our issue of November 1st. Our correspondent in referring to the lode seemed to leave an inference that it was a single lode. The Gold Hill News corrects this statement and says Mr. Rose "speaks collectively of the 'Como lode,' as though all those quartz ledges, large and small, lying within the compass of two or three miles were included in one great mother lode or lode. Mr. Rose may be perfectly correct in his view of it, but the men of 16 years ago who did all the practical mining work that has ever been done in developing the district will hardly agree with him in his hasty, superficial conclusion. There are many promising ledges in the district, some of them large and apparently true fissure veins, which were explored to the depth of from 100 to 200 feet; but nobody was ever able to designate the mother lode of the district. There is a large series of ledges there, considerably varied in character, size and direction, but no main 'Como lode.'

It says also that the *Graphic* of October 24th contains a similar letter from Mr. Rose, in which he says: "The Como lode was worked from 1862 to 1864, and shows the imperfect mining methods of those days. Recently, proper shafts having been sunk, the results have been brilliant." He then goes on to give rich assays from several different ledges, well known to be totally separate and distinct from each other. Full and good assays were obtained from those same ledges 16 years ago, and as for those "proper shafts," which he says have recently been sunk, the ones he makes mention of—the Eureka, Chieftain and West Rapidan—were sunk, together with all the other shafts in the district, 16 years ago, the only one where deeper sinking or extensive work has been done is the old Monte Cristo, now relocated and being worked under the name of the Eureka. From time to time since the first working and abandonment of the district, 16 years ago, attempts have been made by various parties to work some of the ledges or ores of the district, but without success. This year, however, a more general and concerted attempt is being made, all the ledges are relocated and quite an excitement is created. The relocators of the present day work through the old shafts and openings and have merely taken up the work where it was left off 16 years ago. There are many large and very promising ledges in the district, and if the present owners will proceed with the work as well and actively as did their predecessors 16 years ago, they are almost sure to develop not only one, but several valuable bullion-producing mines.

BLACK SEA CANAL.—The gigantic project for the construction of a canal through the Caucasus, from the Black sea to the Caspian sea, is meeting with great favor in St. Petersburg from those interested in direct commerce from the Black sea with Central Asia.

Nordenskjold's Northwest Passage.

Although the world no longer takes such an intense interest in the northwest or northeast passages as was felt in earlier days, when it was believed that if such a route if found practicable would be a short cut from Europe to the Indies, yet Prof. Nordenskjold's feat represents the solution of a highly interesting geographical problem. This distinguished savant all the more deserves his laurels since from early manhood he has devoted himself to explorations in Spitzbergen, Greenland and the north of Europe. The joyful news lately brought was that Nordenskjold had at last got free from the ice which, since September 28th, 1878, had bound his ship, the *Vega*, off Koljutchin shore, almost within sight of open water, and had arrived with all his crew safe and sound at Yokohama, Japan. During their enforced imprisonment, the Professor and his companions unintermittingly pursued their scientific labors, and have reaped a rich harvest of spoils.

The details of the expedition are as follows: Leaving Gothenburg early in July, 1878, the *Vega* spent some days in the Kara sea, and on August 19th doubled Cape Severo or Tchelyukin, the most northerly point of Asia, and which hitherto had never been rounded by man. Mountains rise south of the cape, and animal and vegetable life abound. The *Vega* coasted over a smooth sea, marked on the charts as dry land, to the mouth of the river Lena, and after a glance at the Siberian islands, where the ice prevented any lengthy exploration, turned southward toward Behring's strait, and was finally forced to settle for the winter, on September 28th, at Kolintchin, a short distance beyond Cook's furthest point, Cape Vankarem. Here the expedition were ice-bound for 264 days; but game—bears, reindeer, foxes and wild fowl—was plentiful, and occupations were many. Human society, too, was not absolutely wanting, as only a mile off was land, the Tchutchi peninsula, where there were villages of some 4,000 Tchik-tchi, pleasant, friendly people. The cold was intense; but the expedition enjoyed excellent health and spirits, and not a single case of scurvy occurred. The shortest day experienced lasted only three hours, when the upper limb of the sun alone was visible. On July 18th the *Vega* started again, passing Cape East two days later, and reached Japan without further accident than slight damage from a gale. Prof. Nordenskjold believes that with a little further experience the voyage will be perfectly safe, and considers that no difficulties await skillful sailors between Japan and the Lena, where, as the Lena taps Central Siberia, there is a large prospective trade.—*London Graphic*.

Gold Discoveries in Amador County.

The recent gold developments in Amador county, California, in the Kerkendall mining district, about four miles from Lone City, deserve more than a passing mention. It appears from the *Amador Times*, of the 8th inst., that about six months ago Mr. Wm. Kerkendall, an old resident of this section of Amador county, made the discovery of what is now known as the Kerkendall mining district, although it is not permanently named as yet, we understand. The lead upon which he made the discovery is now named the Sacramento and Kerkendall ledge. On this new vein 1,500 feet were immediately located, and now owned by the Sacramento Gold and Silver mining company, the principal shareholders being Wm. Kerkendall, of Amador county; H. P. Martin, of Woodland; A. J. Burnett, of Sacramento, and a Mr. Wriston. Considerable prospecting has been done, and assays from the very outcrops have ranged from \$7.50 to \$25 per ton, and in many instances at various depths assays have shown all the way from \$20 up to \$357, and in some rare cases much higher. This ledge is 30 feet in width, and is composed of rich sulphurets of a dark color, and is intermixed with fine silver. Claims have already been located on over two miles of this ledge, and fully four miles south just as rich strikes have recently been made. The Kerkendall party are having a smelter, the Robertson process, erected, which will be ready for operation now in a few days, with a capacity of about 12 tons, and a much larger one will be erected soon to keep up with the increasing product of the mine.

A short distance east, and running parallel with the Kerkendall, is the new Peggy Gordon ledge. Several claims have been located on this, and on one a shaft is down 45 feet, with assays proving it to be quite rich.

Immediately west, about 500 feet, and running parallel with the Kerkendall ledge, is the very recent discovered Woodland vein, on which Messrs. H. P. Martin and A. J. Burnett, two energetic gentlemen in mining developments, have located 3,000 feet, and very rich assays have been exhibited.

Still farther west, about 500 feet more, and also running parallel with the Woodland, is the new discovery of the Lone Star lode. This has proven very rich, and was discovered also by Messrs. Martin and Burnett, only a few days since, and these gentlemen with others have located 12,000 feet, and new claims are being taken up daily.

Still west again, and also running parallel with the others, is the newly discovered Savage lode, from which only a few assays have been taken, and this, like the others, seems to contain very rich mineral.

MECHANICAL PROGRESS.

Air Compressor with Water Pistons.

P. Haurcz, in the *Revue Universelle des Mines*, speaks of a horizontal double-acting air compressor, with vertical water pistons designed to obviate the one objection commonly appertaining to air compressors of that class—the low speed at which they have to be worked, in consequence, as has generally been supposed, of the large mass of water to be put in motion at each stroke. The real reason, however, for the speed having to be so limited has, in his opinion, been the neglect of certain special conditions necessary to be observed. The water column in the upright chamber at each end of the horizontal cylinder, in order to act to the best advantage as the air compressing piston, ought to retain a level surface, so as to touch the cover throughout its whole extent at the top of its stroke, leaving no clearance space to occasion loss; instead of which, at even a moderate speed of working, the surface ordinarily becomes violently agitated, and the useful effect is poor. Moreover, the inlet and delivery air valves; when sometimes placed within the extent of vertical travel of the water, disturb its steady movement, interrupting what ought to be the uniform sectional area of the column of water.

In the author's air compressor the speed of the vertical water columns is reduced to half that of the working piston, by making the sectional area of each upright water chamber double that of the horizontal cylinder; and the junctions of the cylinder with the chambers are so arranged as to render the enlargement of area gradual, avoiding any sudden change either of area or of direction. The air valves are all placed in the covers on the top of the upright chambers, and are arranged so as to leave the least possible clearance space. Metal mushroom valves being generally found to get out of order soon and leak, flap valves of leather or indiarubber are here employed by preference. The delivery flap valve beats on a horizontal grid in the center of the cover, and each side is an inlet flap heating on a nearly vertical grid; all the valves give large openings for the passage of the air. The water required for keeping the chambers cool is admitted through the inlet air valves.

Several of these air compressors are now in use, with cylinders of 24 inches in diameter and 40-inch stroke. They work with great regularity, and without any shock, at a speed of 30 revolutions per minute, which can be exceeded without inconvenience. This gives a horizontal piston speed of 200 feet per minute, while the surface speed of the water columns in the upright chambers is only half as much, or 100 feet per minute. The results are excellent, owing to the almost entire absence of clearance spaces, and the avoidance of leakage past the piston. The maintenance is merely nominal, and the useful effect, the author considers, must be superior to that realized by other plans, especially after some time of working, when the pistons begin to get worn.

THE "DYNAGRAPH" CAR.—Mr. Dudley's "dynagraph" railroad car has been making experiments of various kinds upon the Boston and Albany railroad. Mr. Dudley has upon this trip devoted himself mainly to testing the comparative economy of power in the use of 42-inch rather than the common 33-inch car wheels, and the condition of the track of the road. The latter proves to be much better than he expected to find it, particularly the section from Worcester to Albany. The ballast is lighter than on some large roads, notably the Pennsylvania, which is usually considered to have the best road bed in the country. In regard to the wheels, the experiments seem to show that on levels the larger ones are 4% or 5% more economical of power, but on grades there is not so much difference. The data for the calculations are drawn graphically on paper by pens, which are ingeniously connected with the draw-bar of the car, or worked by electricity. The draw-bar is connected with a piston which works in a cylinder filled with oil, the pressure is transmitted through a pipe to another cylinder over a table in the car, and a piston is connected with a pen, which marks on a roll of paper the resistance of the train. Other pens indicate the space passed over each second, each 10 seconds and each minute, each revolution of the driving wheels, each mile passed, the alignment of the road, the quantity of water consumed by the engine, the quantity of coal used, the resistance of the wind, etc.

SAW SHARPENING MACHINE.—The *Revue Industrielle* mentions a new machine for sharpening straight and circular saws, constructed by M. Hure. A grinding wheel is mounted on a rocking shaft which can be inclined in any direction, follow all the profiles of the teeth, and even work around hooked teeth, which is something that cannot be done with other machines. This arrangement also permits of the sharpening of saws with different kinds of teeth without changing the "gummer" for another of different thickness. The pulley which drives the grinding wheel or gummer is mounted on the bearings of the rocking shaft so as to avoid all tension of the cord when the wheel is lowered or raised.

The Anacaptic Table-Lamp.

We have been using for the last few evenings a greatly improved and very effective paraffine lamp, provided with the new split-wick anacaptic burner, introduced by Messrs. Rowett and Sons, of London and Edinburgh. The flame of the new lamp has great body and steadiness, and the combustion is so nearly perfect that no inner chimney is required. The essential feature of the improvement is the exposure of twice the usual surface of the wick to the oil in the reservoir, so that there is always an abundant supply of oil to the flame, and the unnecessary charring of the wick is prevented; the result of this is that the amount of light given off is always uniform, the diminution of the light in this class of lamp usually being due to the accumulation of carbon on the wick interfering with the supply of oil. The mode in which increased suction of oil to the burner is secured is very ingenious; instead of the ordinary single wick the wick-tube is made large enough to receive two side by side. The two wicks placed evenly together, introduced to the lower end of the wick-tube, are caught by the ratchet, and the meshes and threads are so closely pressed into each other that the two wind up and down as accurately and easily as if they were one wick. The parts of the wick below the burner, however, remain separate, and thus there are four surfaces of wick exposed to saturation by the oil instead of only two, as would be the case if only one solid wick were used, and the flow of oil to the flame is thus more continuous and abundant. As proofs of the efficacy of this improvement, a lamp with the reservoir only half or quarter full, or if there be any oil in it at all, will, on being lighted, give as large a flame as if the reservoir were filled up, whereas to get an ordinary lamp to burn at all well the reservoir must be quite filled up before lighting, and also the split-wick will burn the oil out to the last drop without any diminution in the size or quality of the flame. The tops of the two wicks must, of course, be quite level and even with each other, and if one should get higher than the other they can be made level by holding the wick with the finger farthest from the ratchet either up or down as required. The lamp is no more troublesome to attend to than any other paraffine lamp, provided ordinary care be used and cleanliness be strictly observed there will never be cause of complaint, as the light given is considerably greater than that of an ordinary gas burner. The arrangement is altogether worthy of high commendation.—*London Mining Journal*.

Transfer Lathe.

It is frequently necessary in the arts—for instance, in making the copper, iron or steel rolls for calico printing, or the embossing rolls for leather, cloth, sheet zinc, brass or other sheet metals—to transfer any design from small pattern rolls to the large ones upon which the design is to be engraved. To do this work rapidly, cheaply and with accuracy, transfer lathes are used.

The lathe is generally driven by power, but it can be run also by hand by means of a crank or lever. It has a counter-shaft overhead and is reversible. Conical centers are placed on the center shaft to hold the roll on which the transfer is to be made. These centers are movable to suit rolls of different lengths, which are placed on and are taken off by raising one end of the shaft. Attached to the end of this shaft there is an index wheel, which is used to lay out the work accurately, and with the aid of a full set of cut gearing, which is furnished with the lathe, the operator is enabled to move the rest at any given pitch. The steel roll on which the design is engraved is placed in steel journals ground perfectly true and fitted in the head of the rest. It is then brought to bear upon the copper, iron or steel roll which has been placed upon the center shaft, the lathe is put in motion and the design required on the roll is thus transferred from one to the other. The pressure required to make the indentation on the roll is regulated by a weight placed in the hook on the bar attached to the rest. The lathe is furnished with composition boxes, and the small parts, together with the shafts, are made of steel. As the workmanship must be very accurate, all the parts are made to a gauge, so that there may be no lost motion or jar, the slightest defect being sufficient to destroy the impression made while transferring the design from the small steel roll to the roll which is used to do the printing or embossing.

FLUME FOR CORD WOOD.—The manager of the Burlington and Lamoille railroad, in Vermont, has in use an ingenious method of conveying cord wood a distance of two miles and landing it on the cars. He has erected a small flume from a point near the timber leading to the station. A stream of water from a brook is turned into the flume and the wood floats down very rapidly, and at the terminus is shot on to the cars, while the water falling short flows away into the river. Thirty cords of wood are placed on the cars in this manner every day.

AN OCTOPLEX PRINTING TELEGRAPH.—Prof. Klinkerfues, the director of the Göttingen Observatory, has, it is said, taken out a patent for a new invention in telegraphy. The professor has discovered a method by which up to eight different messages may be sent simultaneously by the same wire, an apparatus at the receiving end printing the messages separately and all at the same time.

SCIENTIFIC PROGRESS.

A New People.

The Arctic explorer, Prof. Nordenskjöld, found a new race of people in the Arctic regions in latitude 67° 7' north, longitude 137° west from Greenwich. They are known as the Tschuktschi, and are described as savages because their civilization is not very far advanced. But the Professor is enthusiastic in his testimony to their excellent qualities—social, domestic and national.

They are described as distinctly differing from the Esquimaux tribes; and though it is not yet decided to what race they belong, they are thought to be related to the Kamchatkades and Koriaks.

Some very interesting and valuable details have been collected by Nordenskjöld and his staff as to their ethnography and history. About 250 years ago they were distinguished and gallant warriors. The discoverers have gathered a valuable assortment of the arms and armor of that period. Many of these implements are preserved among the families, whose habits are no longer aggressive. Very noticeable are their cuirasses, carefully wrought out of mammoth ivory, and fashioned with a remarkable resemblance to the old Roman panoply. Their spears and bows are made of whalebone, wood and ivory, spliced and bound with the sinews of the reindeer, and showing an advanced perception of artistic ornamentation on the part of the makers. One hundred and fifty years ago the famous Russian, Col. Paulovski, commanded an expedition sent against them from Siberian settlements. In his first engagement with them he was badly worsted. He subsequently defeated them, but with heavy loss to his own troops, and has recorded much such a tribute to their valor as Pyrrhus bestowed upon the Italian legions which he overthrew. A mild form of disease is averred by the natives to have been left behind by his soldiery and to be still in existence.

Strangely enough they have no government, no laws, and almost no religion, if any. A Russian starost is their nominal ruler, but has neither authority nor influence. In fact, there seems to be no necessity for the exercise of either the one or the other, for his subjects are evidently an exceptionally excellent and well-disposed people. The foreigners were on terms of intimacy with thousands of them, and never saw or heard of a single case of quarreling among them. Perfect harmony prevailed in the villages and families. Women have great influence, and are treated by the men in all respects as their equals and with much politeness and deference. The language spoken by this tribe is peculiar, and, as far as has been yet determined, shows no affinity to others.

The features are less Mongolian in type than are those of the Esquimaux or the other indigenous tribes of Siberia. The hair is generally, but not invariably, black, and the complexion is decidedly light. Young women are often very fair, handsome, and of perfect symmetry and fine proportions. The men are tall, above the average height of man's growth, some of them attaining to very little short of the splendid statue of the best specimens of humanity in northern Europe. One woman is mentioned to me as being of gigantic size, so large, in fact, that she might well be shown for money. One of Nordenskjöld's attaches has a note—I regret at this moment inaccessible to me—of her height and bulk, the former being over seven feet. They are omnivorous in their diet.

PRINTING AND LITHOGRAPHIC INKS.—Two kinds of varnish are employed in the manufacture of printing inks: the one obtained by boiling linseed oils, and the other from a mixture of resin and resin oil, the latter being chiefly used for newspapers where rapid drying is of importance. M. Lorilleux allows his linseed oil to rest for two years at a constant temperature. It is then boiled by means of hot air at a distance from the furnaces, so as to remove every risk of fire. A mass of 2,500 kilos is boiled from 25 to 56 hours, and is stirred by a mechanical agitator. The varnish thus obtained is limpid, and flows well. The lamp-black is produced either by means of specially constructed lamps, or by the decomposition of naphthalin oils, which fall by drops into a heated retort. The gaseous products are carried off by tubes, at the end of which they are burnt under sheet-iron bells, while the black is carried off by a current of air into large chambers. It is afterward submitted to calcination.

NEW POCKET LENS.—An English optical instrument maker has just invented a wonderful pocket microscope, upon which scientific writers are conferring much praise. The new lens consists of three lenses, the interior grooves of which are almost transparent; they are lined by transparent cement, which has a refracting index corresponding very nearly with the glass. In this way no light is lost by refraction from the surfaces of the curves. The peculiarities of this remarkable invention are that it focuses three times as far from the object under examination as either the Stanhope or Codrington lens. By this means scientists and others using the microscope can examine opaque objects as well as transparent ones, as the light can be conveniently allowed to fall upon them at any required angle, as the definition is exceedingly sharp.

Theory of the Telephone.

An article lately appeared in *Nature* from Percival Jenks, of British Columbia, which gives the result of some experiments made by that gentleman with the telephone. He says:

Experiments that I have recently made with a Bell telephone, have convinced me that the sounds produced are the result of molecular change in the iron disk, and are the same in kind as those heard in the telephone of Reiss.

My experiments were made with a carbon transmitter and Bell receiver, using a small battery to generate the current. First I removed the bar magnet from the receiver, in accordance with a suggestion made by a writer in *Nature* some months ago. The effect without the magnet was the same as with it. It then occurred to me that the intensity of the sound might be increased by using two disks instead of one. Accordingly I cut two circles out of a piece of sheet iron, leaving a narrow strip of the metal to connect them, of sufficient length to ensnare the disks to lie on either side of the reel, so as to form, in fact, an armature to the electro-magnet. On experimenting with this my anticipations were fully realized, the sound produced being more than double that from a single disk.

Now, while trying these experiments I held the disks loosely in my hand, without their being in any way fastened to the wood holding the reel, the effect being the same as if firmly secured. In fact, a common dinner knife or a rough piece of iron would emit sound if brought near enough to the core of the electro-magnet.

I have since constructed a very efficient telephone receiver out of a block of wood two inches square and three-quarters of an inch thick. I then drilled a hole sufficiently large to receive the reel, and covered the block with thin sheet iron. It needs no ear-piece, and forms the most effective telephone receiver that I have seen. But, still further to prove that the sounds produced are due to the magnetization of the iron of the disk, and not to mechanical vibrations resulting from the electro-magnet, I made an iron reel, the flanges of which were two inches in diameter. Now, on covering the reel and placing it in circuit, the flanges of the reel gave out sound as clearly as in the Bell telephone. In my judgment this experiment renders it conclusive that the sounds proceed from the magnetization and demagnetization of the iron, and are therefore precisely the same in character as those formed by a Reiss receiver.

CHLORINE, BROMINE AND IODINE.—The three bodies should exist in solution in the state of chlorides, bromides and iodides. If wholly or partly present as chlorates, etc., they must be reduced by treatment with an excess of sulphurous acid. The mixture, acidulated with sulphurous acid, is treated with a slight excess of a mixture of bisulphite of soda and sulphate of copper. The iodide is precipitated immediately and very completely as cuprous iodide, in which state it may be directly determined with much accuracy. The results are liable to be erroneous only in presence of sulpho-cyanides—a circumstance not to be expected in practice. After filtering off the cuprous iodide, the liquid is boiled with an excess of sulphuric acid until all the sulphurous acid of the sulphites has been completely expelled. When this is effected, the liquid is introduced into a flask which communicates by means of a bent tube, with a Will and Varentz's nitrogen-tube. Into this is introduced a solution of bisulphite, or of sulphurous acid, or bisulphide of carbon, or, if it is preferred, a solution of potassium iodide, and the tube is kept in cold water. To the liquid in the tube is added a small excess of pure chromic acid, and a mixture of sulphuric acid and potassic bichromate, and the liquid is boiled until the bromine is completely expelled. It is then determined, either as bromide of silver, or by a colorimetric process, or indirectly by the volumetric determination of the iodine which it liberates. To determine the chlorine it is merely needful to reduce the excess of chromic acid by means of a sulphite, and to precipitate with silver nitrate.

CARBIDES FROM PETROLEUM.—The light petroleum, if submitted to dissociation by heat, become a source of incomplete carbides of different orders, less rich in carbon than the formic carbide, but capable, if the action of heat is sufficiently prolonged, of recombining among themselves so as to form more complex compounds. Among the incomplete carbons ethylene, propylene, butylene, and acetylene have been recognized. They are accompanied simultaneously by the ulterior products of their polymerization, or of their reciprocal combination, benzol, ethyl-acetylene, or crotonyl. By a novel application of the general method of solvent products have been fractionated according to a principle very different from that of a fractionated distillation and crystallization. In this manner each of the industrial products may be resolved into a great number of carbides, among which are anthracene, phenanthrene, chrysene, pyrene, chrysogren, benzerythrene, etc.

A NEW BASE.—A new base has been obtained by C. Bottinger. It is obtained as a product of the reaction of benzol-chloride with aniline. On heating the base with mercuric chloride, or with arsenic acid it is converted into a true coloring matter. In the former case the solution is first clear, and then reddens, the coloring matter being developed with a brisk reaction. The crude dye is a reddish violet.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals.

Mining Share Market.

An unusually weak and dull market has been the feature of affairs for the past week. Sales have neither been rapid nor large, nor have the fluctuations been remarkable. A feeling of confidence seems, however, to be prevalent, as we go to press, especially in the Comstock, the prices being helped by the raising of ore, some 400 tons being shipped from the Sierra Nevada to the mills for reduction. The present aspect of the stock market may generally be attributed to the investment of capital in other branches of business, or its retention to await future events. It is not certainly being invested to any extent in stocks. The same feeling seems to pervade the New York and Chicago markets, and the cause may possibly be attributed to a general depression.

Seeders and Planters.

By permission of the Commissioner of Patents, Mr. James T. Allen has made a digest from the records of the Patent Office, of all the American patents on seeding machines and implements granted from A. D. 1800 to January, 1879. This volume is the only one ever published comprising this class, and has been prepared with great care and labor. It contains thirteen hundred and twenty-five pages, and embraces nearly four thousand patents. Each drawing is clearly and distinctly photographed, and can be as readily understood as the copies furnished by the office. It also comprises all the reissues and additional improvements granted during the above period, accompanied with the full claim, and also brief when found to be of service. Especial care has been bestowed on the arrangement of patents to simplify and facilitate examinations, and to this end the patents have been arranged chronologically under the official classification of thirty-four subdivisions.

In addition to this are complete and convenient indexes of each subdivision, whereby the drawing or claim of any patent may be found by name, number or date. There are also complete lists of models saved wholly from the fire of 1877, and of those reclaimed from the debris of the conflagration.

Inventors, manufacturers and attorneys will see the great advantage a work of this kind affords, particularly to those residing at a distance, enabling any one to make examinations nearly as quickly and thoroughly as if consulting the office records. The number of volumes of the Digest is limited to a few hundred, most of which has been taken by subscribers. The price has been fixed at the low rate of \$25 per copy, whereas the patents it contains could not be purchased for less than \$375 to \$400.

Those desiring copies of this exhaustive treatise are requested to send their orders at once, remitting by postal order, check or draft, or copies can be sent by express C. O. D. A liberal discount is made to libraries. Mr. Allen's address is room 116, Patent Office, or lock box 699, Washington, D. C. Reference is made, by permission, to the Patent Office officials.

The Miners Jubilant.

There has been a certain depression in the mining interests during the litigation of the farmers against the miners in the mining debris suit, more particularly in those localities threatened with immediate stoppage of work, in case of the decision of the lower court being sustained. On receipt of the news of the reversal of the decision by the Supreme Court, thus deciding the momentous question against the farmers, the mining communities in the different counties, where hydraulic mining is carried on, were exceedingly jubilant. At Nevada City one hundred guns were fired, bells were rung, flags hoisted, bombs and crackers hurled, and everybody rejoiced. A dispatch from Grass Valley says: "The dispatch announcing the favorable issue of the suit was received throughout the county with enthusiasm. Cannons were fired, flags raised and fire bells rung, while every steam whistle in the neighborhood added to the general uproar. The streets of this place have all day been thronged with eager and excited crowds, handshaking and congratulating over the result. Even John Chinaman seemed to appreciate the situation, and in no small degree assisted in the joyous demonstration by the firing of bombs and exploding of fire-crackers."

A COMPANY has been organized at Salem, Or., to rebuild the woolen mills which were burned two years ago.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

CONY. - Ledger, Nov. 15: Draining the shaft at this mine is making satisfactory headway. The water has been taken out to a point below where the timbers have to be renewed. There is still an immense body of water to be taken out; and weeks will yet have to elapse ere the work is completed. The erection of the 40-stamp mill has been fairly commenced. Some 9 or 10 carpenters are employed fitting the frame work. The company has decided not to let out the work by contract. Nearly the whole of the castings and machinery for the mill will be brought from San Francisco. The mill is to be first-class in every respect, and be supplied with steam power. The rails of the past week have interfered with the grading operations on the mill-site, and with the carpenter work. It is not probable that the mill will be in running order much before the opening of spring.

WATER. - Basis. - How to manage the vast body of water is still an unsolved problem with this claim. A second-hand steam pump was brought from below, but was found to work badly, and had to be discarded. Another pump was obtained from Oneida, and fixed up last week, but this is not altogether satisfactory, and doubts are entertained about controlling the water with present pumping facilities.

KIRKENDALL DISTRICT. - This new mining district is situated about four miles from Lone City, and is rapidly assuming a prominent place among the gold-producing districts of this county. It is located away to the west of what is known as the mother lode. The Sacramento and Kirkendall ledge is said to be 30 ft wide, the value of which, as shown by actual assays, ranges from \$7.50 to \$20 per ton. The owners are having a smelter erected, with a capacity of 12 tons per day. This smelter will be ready to commence operations in a few days. Other promising claims are the Peggy Gordon, Woodland and Lone Star—all rich in gold according to assays.

SOUTH SPRING HILL. - At this claim, near Amador City, a shed, 30x30 ft, has been erected over the hoisting works. The hoisting works consist of a patent horse power, all made of iron.

VOLCANO PRESS. - The big tunnel is being pushed along as fast as circumstances will permit. The work has been retarded considerably of late on account of bad air, and it has been found necessary to put in air pipes for ventilation. The rock in the face of the tunnel is very hard, and progress is consequently slow. At the Golden Gate mine, a three-ft ledge of rich ore has been struck, and the prospects for a paying mine are excellent. The mill is being hurried up.

VICTORIA. - The contract for sinking the shaft is completed. The shaft is now down 260 ft. No ledge is visible, although in sinking, large boulders of quartz would come in from time to time, and then pinch out. The contractors had good sinking ground, and made fair wages. The Victoria has the finest shaft in this section. It is 7x4 in the clear, timbered in the most substantial manner. Over the shaft there is an excellent wharf. It is proposed to crosscut for the ore body, which is thought to be close to the shaft.

REVER MINE. - At the bottom of the old shaft some fine-looking quartz was found, the ore showing from three to four ft in width. In sinking also, some rich rock was encountered. There is a strong flow of water in the shaft, which is too much to be controlled by windlass. The shaft is 40 ft deep.

PROXER. - Splendid ore has been taken out of this claim. Some specimens are sprinkled with free gold, and the estimated yield of the rock is placed at \$20.

THE WEBSTER. - Is making slow progress. No ledge of any size has been met with as yet. Small strata of quartz are occasionally cut, some of them rich, but not rich enough to follow.

BARLOW. - This is situated on the Middle Fork of the Consumnes, and is turning out quartz of fine grade. Several other mines near Nashville are also panning out pretty well.

PHOENIX. - This grand mine is turning out its usual quantity of gold. The mill is running to its full capacity. The south shaft is now down 1,200 ft, the contractor having 40 ft more to sink to form a pump. At present the men are cutting out a station. The slate is very hard.

CAVALERAS. -

MANMOUTH. - Work was commenced on this hydraulic last week.

SAFE DEPOSIT. - Important improvements are making at the Safe Deposit mine, Old Woman's gulch. A new tunnel has been run to the channel further down the ridge—low enough to drain the mine without the expense of pumping. The new tunnel will be about 350 ft in length; is already run to the outer edge of the channel and will be completed in a few days. The mill belonging to the mine is being moved to the mouth of the new tunnel and will be in readiness for crushing the gravel by the time the mine is "in fix" for taking it out.

EL DORADO. -

ROSE. - *Republican*, Nov. 13: In the Rose mine, connection between the 200 and 300 levels have been made, and a fine body of rich ore has been developed. Sinking will now be resumed and the further development of this ore body carried on at the same time.

P. O. Q. MINE. - At the P. O. Q. mine (Old Pacific), work upon the mill and hoisting works is being driven as rapidly as possible, and about six weeks, when it will probably be then completed, when a large additional force will be put in the mine. Before spring the company will have about 60 men in its employ.

ROSECRANS. - At the Rosecrans the hoisting works have been in operation about two weeks, and the mill is about completed and will probably be started up the last of this week, perhaps sooner. Sinking is now in progress and there is no doubt about the mine being a good paying one.

ROBINSON. - The Robinson gravel mine, which has yielded its millions in the past, is now surpassing its previous yield, a new pay channel having been developed. In this mine the gravel is found about 100 ft below the surface, and is milled. The last clean-up, after seven days' run, produced \$8,200, and the indications are that this rate will be kept up for some time.

MONO. -

NOONDAY COMBINATION SHAFT. - *Bodie News*, Nov. 16: The shaft is now down 503 ft; progress made during the week, 16 ft. The rock is hard but breaks well. The water is easily handled, and has not increased as depth is gained. The east crosscut from the 172 level is in a formation favorable; progress made during the past week, 30 ft. Drift south on vein No. 2, same level, in 112 ft; progress during the week, 23 ft. The ledge is three ft wide, the ore of high grade. Drift north, same vein and level, in 87 ft. The ledge is four ft wide of good milling ore. On the same level, drift No. 1, south on vein, in 165 ft. The ledge is three ft wide of clear, bright, good milling ore. The drift south on the 212 level in the vein 138 ft. The ledge large and strong, fully six ft wide of high-grade ore. The machinery is working well. The arrangements for working this mine are perfect and complete, and give evidence of that experience so essential to the proper development of mining properties. The new boilers for the water wheels are of clear, bright, good milling ore. The drift south on the 212 level in the vein 138 ft. The ledge large and strong, fully six ft wide of high-grade ore. The machinery is working well. The arrangements for working this mine are perfect and complete, and give evidence of that experience so essential to the proper development of mining properties. The new boilers for the water wheels are of clear, bright, good milling ore. The drift south on the 212 level in the vein 138 ft. The ledge large and strong, fully six ft wide of high-grade ore. Carbonate Ore Fields.

A late issue of the *Leadville Chronicle* contains an interesting article from T. A. Green, upon the subject of the "Carbonate Ore Fields." Mr. Green says:

There are three things which seem to have been absolutely necessary to the formation of our immense carbonate veins or beds, viz.: Carboniferous limestone, porphyry and intense igneous action; and there are four things to look to in order to find our carbonate veins or beds—alternating layers, or strata of lime and porphyritic rock, igneous or heat action, and heavy beds or veins of iron. The iron in these mines is the matrix or gangue mineral, bearing the soft carbonates, and it may be found above, below, or running through the soft carbonate veins or beds, or it may be so strong in places as to cut out the soft carbonates. And then again the whole vein may turn to soft carbonates. If I am mistaken as to the iron being the matrix or gangue, it anyhow accompanies the soft carbonate everywhere, and in all veins, beds or deposits—the three metals have been formed in the same veins or fissures—lead, silver and iron. A large part of this iron is hematite, or specular and comprised of about 70 parts of iron and about 30 parts of oxygen; but originally it was all carbonate of iron, and has, in the course of ages, grown or changed into its present form.

Now, in order to find rich veins or beds of carbonates, look for heavy alternating layers of lime and porphyritic rock, heavy beds or veins of iron and igneous action—the greater the signs or evidences of igneous or heat action the better. I examined the Loveland mine on Mosquito mountain a short time ago, and I found much of this mineral like the cinders of a furnace. This was a good sign or indication, and although I found no carbonates, the mine promised to be very rich in other forms of silver ore. In fact, so far as then developed, it was a most remarkable mine.

The first and most important rule I can lay down for the guidance of the prospector, is to find out from the outcrop on the side of the hill or mountain, and from other shafts in the neighborhood, if there are any deep enough, where the contact is, or as near where it is as possible, as he must not expect to find rich beds of carbonates except at or near a contact. To illustrate: I went out to examine a certain mining locality on the side of a moderately steep hill or mountain, and I found a heavy porphyritic stratum about 200 feet in thickness, cropping out all along—rather around—the side of the mountain, and a number of prospectors had commenced work on the very top of this thick stratum, where they would have to sink at least 200 feet before they could possibly strike a contact and mineral, and work all the way through this hard rock by the slow and expensive process of blasting, which was enough to dishearten and discourage almost any poor prospector. I then went down the side of the mountain till I thought I was quite 200 feet perpendicularly below where the miners had commenced their shafts, and I could clearly trace a well-defined contact for half a mile around the mountain, and although this contact was slightly covered with drift beyond that, yet it could be approximated for a mile further. Now, if these miners had examined for this contact, which they could have easily found, and made some cuts along the edge of the contact, or sunk a few shallow shafts and then drifted in on the contact, they would soon have either struck mineral or have proved that there was none there. About two-thirds of all prospecting work done in this camp is wasted in the manner above stated; and I maintain that this could be avoided by a little judgment and experience. There are also hundreds of miners in this camp prospecting entirely outside of the carbonate belt where they cannot possibly find rich and paying beds of carbonates. A rich mining belt like this will throw out pockets and small veins from five to ten miles on all sides, and throw out a coloring; but unless heavy and alternating layers or strata of lime or porphyry, and an abundance of iron are found, I do not think there is much use prospecting for carbonates, but other kinds of gold and silver ores may be found. Porphyry alone, or limestone alone, or mere fragments of both will not do, nor will mere stains and traces of iron do.

The grander the scale on which you find porphyry, lime and iron, the better your chances for rich carbonate beds.

Almost any miner ought to be able to distinguish lime and porphyry; but there is white lime rock in some places that looks very much like porphyry, and besides nearly all the rock of which these vast mountains are built is metamorphic; but still the miners may learn to generally distinguish lime from porphyry; and this is important.

It seems to be a disputed question both amongst our experts and our courts as to whether our carbonate veins are vertical or horizontal, and in a legal point of view this is a very important question, but it is very strange indeed that there should have ever been any doubt or controversy about it, at least as a scientific question. No horizontal veins of coal or any mineral run on an exact horizontal level; all such have various dips and many undulate like waves, or a rolling surface. Judge Hallet has defined a vertical vein to be any variation—an inch or a foot—from a horizontal line. This substantially decides that there is no such thing as a horizontal vein of coal or any other kind of mineral on the globe. It might just as well be said that

any variation from a vertical line—an inch or a foot—is a horizontal vein, and then there could be no such thing as a vertical vein on the face of the globe. The able and learned Judge was certainly mistaken in his definition, and will yet correct it, as important legal rights depend on it; millions of dollars in this camp hang upon that definition.

As these carbonate veins or beds of mineral are wedged in between great horizontal layers or strata of lime and porphyritic rock, how can they possibly be vertical rocks? It is true that where carbonate veins outcrop in the sides of the mountains they may have a heavy dip until they get under the heavy portions. The mountains in settling back were much heavier in the center than at the edges and sides, and consequently the veins are pressed down further in the centers of the cones or mountains, and they bow up at the ends or outcrops on the sides of the cones or mountains. Therefore the veins dip rapidly for the first few hundred feet going into the mountain on either side. When these cones and mountains were first upheaved they were also looser in the center than at the sides, and pressing down these metallic veins in the center with them. It must be remembered that even these "everlasting mountains" are not altogether firm and stationary, but have been gradually settling down for millions of ages, and are still settling down. They are also being gradually dissolved and worn away on their sides and tops by the elements around them and the rains and snows upon them, and all the rocks of which they are built are continually changing by the chemical agencies in operation both within and around them.

The forces of nature which operated here and upheaved the vast amphitheater of hold, rugged, snow-crowned mountains, and cut them into cones, gulches and great chasms, were on a grand scale, and it was the same grand forces of nature that prepared the openings and great fissures in the rocks to receive our immense mineral deposits; and the chemical agencies or elements which operate in the vast laboratory of the earth to fill these great openings and fissures with mineral were also on a grand scale, and the man who thinks these wonderful agencies only operated in a few spots here and there, and that these particular spots have all been discovered, has but a poor conception of the forces, laws and chemical agencies of nature and of the earth. Even the immense iron houlders, some of which are almost as large as a small house, scattered all over this carbonate belt, and the great ledges of iron that crop out in places on our cones and mountains, stamp this as one of the grandest mineral belts in the world. This alone is sufficient evidence of the grand scale on which these mineral deposits have been gotten up. The further fact that there are carbonate veins or beds developed here from 200 to 300 feet in width, and from 25 to 50 feet in thickness, and which seem to be almost inexhaustible, attest the grand scale of this whole mining belt, and the chemical agencies which operate here to produce them.

TO VULCANIZE INDIA RUBBER.—The vulcanizing process, patented by the late Charles Goodyear, consists in incorporating with the rubber from 3% to 10% of sulphur, together with various metallic oxides, chiefly lead and zinc, the quantity of the latter articles being regulated by the degree of elasticity, etc., required in the desired article. The goods of one large establishment are vulcanized in cylindrical wrought-iron steam heaters over 50 feet long and from 5 to 6 feet in diameter. These heaters have doors opening on hinges at one end, and through these doors the goods to be vulcanized are introduced on a sort of railway carriage, then, after the door is shut, steam is let on, and a temperature of from 250° to 300° of heat is kept up for several hours, the degree of heat being ascertained by means of thermometers attached to the heaters. The value, solidity and quality of the goods is much increased by keeping the articles under the pressure of metallic molds or sheets while undergoing this process. The whole process requires careful manipulation and great experience to conduct it properly.

SINGULAR CAVE.—The *Courrier de Nemcen* (near Algiers) states that some miners occupied in blasting rocks in the vicinity of the picturesque cascades, discovered the entrance to a cave, the floor of which was covered with water. They ventured upon the subterranean river on a raft, and followed it some 60 meters distance, when it disappeared in a vast lake. Here the vault of the cave was very high and covered with stalactites. In many parts the miners had to steer their raft between colossal stalactites which reached down to the surface of the water; eventually they reached the end of the lake, where they noticed a canal extending toward the south, and into which the waters of the lake flowed. The workmen estimate the length of the lake to be two miles and the breadth about one and one-eighth miles. They brought out a quantity of fish, which, they say, surrounded the raft, and which were found to be blind.

EMIGRATION OF POTTERS.—A pottery firm in Staffordshire, England, have decided to remove their seat of manufacture across the water with a view of locating in Philadelphia. Arrangements are now being made to close up the home works, and the workmen are preparing to settle in a new land. The party will, in all probability, arrive here before Christmas. Several owners of potteries are considering the desirability of permanently settling in the United States.

Fish Farming in Nevada.

The average citizen of eastern Nevada, says the *Eureka Leader*, has but little conception of the mammoth proportions that the fish industry and culture is assuming under his very nose. We say culture, from the fact that fine fish are not a native of Nevada, and like other imported articles, whether of the finny tribe, or what not, have to be brought from abroad, tended and raised with much care. All of this is a preface to what the *Leader* has to say in regard to the aquarium of H. C. Fenstermaker. Mr. Fenstermaker owns a tract of 600 acres of land, 20 miles directly south of Eureka, at the head of Fish creek. In other words, Fish creek rises on his premises from numerous springs, which center and make the stream some 80 rods before leaving his property, in an easterly course, thence finding its way towards Mr. Page's ranch and Pancake valley. His dominions are surrounded on either side by tall mountains, partly wooded, and it would seem that the valley had at one time been an immense lake, which, by natural changes, had become overgrown by vegetation, large and small springs alone being left as an outlet to the immense body of water that finds its way through the valley by subterranean passages, breaking out here and there as above described. There are some 12 large flowing springs, with about 15 lesser ones, making a chain of lakes that would float a small clipper ship. About two years ago, Mr. F. conceived the idea of raising fish, and, with this object in view, procured from United States Fish Commissioner Myron Greene, Shasta county, California, on May 1st, 1878, some 600 eggs, known as the McCloud River trout. These he put into one of the small springs, and a few days thereafter was delighted to find that they had hatched, and the water was filled with an innumerable number of little trout. These he carefully watched, but for the following six weeks they derived nourishment from the yolk, or egg, that yet remained immediately under their throats. After this they were carefully fed on the yolks of eggs, grated liver, etc., until they had gained a little age and strength, when they were removed to a larger spring and allowed to care for themselves, subsisting on little chubs, shrimps, etc., which are natives of the springs. The trout being of the voracious nature of the shark, rapidly grew, and to-day they will weigh from two to four pounds. It is estimated that they grow about one inch every month.

Mr. F., being encouraged with his experiment, and also learning much from observation and reading, again sent and received 10,000 eggs from the same place, and was gratified to see them nearly all hatch, and about a month ago transferred the little fellows from the hatcher to the large lakes. The hatcher somewhat resembles a sluice box for placer mining. It is a trough about one foot square, with cleats at intervals on the bottom, over which a small current of water is allowed to run. Last March he secured 37 small carp from a fish grower in Sonoma county, Cal., paying \$75 for the same. This species of the finny tribe, hatches so soon that they alone are transported when young. Those placed in these springs have since spawned, and are doing nicely. Last April he sent and got 22 little catfish (frys), which he placed in his springs, and to-day the largest will weigh over four pounds. At the same time 12 small gold fish were secured as an experiment. They are also doing well, but their future is yet to be learned.

In these lakes Mr. F. has upward of 11,000 fish, a large majority being of sufficient size to be marketed. Arrangements have been made for 45,000 Lake Michigan whitefish spawn, which will be here about the last of November, and also for a lot of soft-shell turtle and different species of the bass. Mrs. F., who is a great enthusiast on the fish question, takes much pleasure in tending her different finny bevies, many of the larger fish being regular pets. It is well worth one's time to make a visit to this ranch of lakes and fish, and the industry promises to be a most remunerative one. The fish can be raised with little trouble, and when a few weeks old find plenty of food in the rich mud grass, chubs and shrimps that surround and inhabit the lakes. The springs look beautiful, and even at this late day of the season there floats on the water's surface a green, viney vegetation resembling lettuce, which the fish eat and gambol about, often springing several feet out of the water. One can have no conception of the attraction here afforded the curious, unless by personal observation, and our readers have but little idea of the magnitude of the enterprise.

NEW YORK INVENTORS' INSTITUTE.—Peter Cooper has passed over \$30,000 to the Cooper Union, in New York, for the purpose of adding another story to the building, which will be occupied by the Inventors' Institute. The work will be completed by December. The object of the Inventors' Institute is to give the inventors the free use of a library of all the works which they may desire to consult.

STEAM ON CANALS.—Locomotives are used on canal towpaths of France. They are of light build, not weighing over four or five tons, and are managed easily by one man. Barges are thus drawn at a speed of two miles an hour—about twice the mean rate of a horse on the towpath. An empty vessel is drawn six miles an hour, but a greater speed would damage the banks of the canal.

Traveling Rocks in Canada.

Lord Dunraven, in an article in the *Nineteenth Century*, thus describes a curious phenomenon observed by him in Canada: A strange scene, for example, which came within my observation last year, completely puzzled me at the time and has done so ever since. I was in Nova Scotia in the fall, when one day my Indian told me that in a lake close by all the rocks were moving out of the water—a circumstance which I thought not a little strange. However, I went to look at the unheard-of spectacle, and, sure enough, there were the rocks apparently all moving out of the water on to dry land.

The lake is of considerable extent, but shallow and full of great masses of rock. Many of these masses appear to have traveled right out of the lake and are now high and dry some 15 yards above the margin of the water. They have plowed deep and regularly defined channels for themselves. You may see them of all sizes, from blocks of (say), roughly speaking, six or eight feet in diameter, down to stones which a man could lift. Moreover, you find them in various stages of progress, some 100 yards or so from the shore, and apparently just beginning to move; others half way to their destination, and others again, as I have said, high and dry above the water. In all cases there is a distinct groove or furrow which the rock had clearly plowed for itself. I noticed one particularly good specimen, an enormous block which lay some yards above high-water mark. The earth and stones were heaped up in front of it to the height of three or four feet. There was a deep furrow, leading down directly from it into the lake, and extending till it was hidden from my sight by the depth of the water. Loose stones and pebbles were piled upon each side of this groove in a regular, clearly-defined line. I thought at first that from some cause or other the smaller stones, pebbles and sand had been dragged down from above, and consequently had piled themselves up in front of all the large rocks too heavy to be removed, and had left a vacant space or furrow behind the rocks. But if that had been the case the drift of moving material would of course have joined together again in the space of a few yards behind the fixed rocks. On the contrary, these grooves or furrows remained the same width throughout their entire length, and have, I think, undoubtedly been caused by the rock forcing its way up through the loose shingle and stones which compose the bed of the lake.

What power has set these rocks in motion it is difficult to decide. The action of the ice is the only thing that might explain it; but how ice could exert itself in that manner, and why, if ice is the cause of it, it does not manifest that tendency in every lake in every part of the world, I do not pretend to comprehend. My attention having been once directed to this, I noticed it in various other lakes. Unfortunately my Indian only mentioned it to me a day or two before I left the woods. I had not time, therefore, to make any investigation into the subject. Possibly some of my readers may be able to account for this, to me, extraordinary phenomenon.

Hydraulic Mines Enjoined.

It is said by the *Grass Valley Union* (Nevada county), of the 8th inst., that a report was brought down from the Ridge on the 7th, "coming from what was believed to be good authority, that an order had been issued to stop work in the mines of the Milton and Eureka Lake companies, and to shut off the water from the canals of those companies. It was not known whether similar instructions had been given by the North Bloomfield company. These orders were said to be in consequence of the writs of injunction granted against the hydraulic companies by Judge Keyser, in the instance of the suit of the city of Marysville. The three companies named are the heaviest gravel mining incorporations of the county, and if it be true that they have shut down, and will remain so for any length of time, or during the pendency of the suit, the effect upon the business interests of the Ridge will be seriously and unfavorably felt."

If the above report be true, it indicates that the solution of the debris question is well under way. The mere fact that a restraining order has been granted cannot indicate in any respect the leaning of the court so far as a final decision upon the merits is concerned. Besides, the injunction at this stage of the case would be only preliminary, and might have been granted *ex parte*, in which case it would be apt to be set aside on motion. In any other view a substantially strong case would have to be made out before the court would grant the order.

It may possibly occur that there are exceptional cases where the accumulation of mining debris through hydraulic mining has caused sufficient damage to enable the court to perpetually enjoin on a final hearing. But any decision will necessarily be founded upon the facts in every particular case, and can have no general bearing upon the question as to whether hydraulic mining is a universal public nuisance.

It will require some action on the part of the Legislature to fully determine the rights of both parties, and that such action will be taken by the next Legislature is quite certain, if we may judge from the pressing necessities of the case.

THE ENGINEER.

Iron in Engineering.

The rapid development of the railway system from its initiation by George Stephenson in 1830, has called out all the resources of the engineering mind, and led to bridges and viaducts of great boldness and skill. One of the most celebrated of these is the tubular bridge over the Menai, having two spans of 400 feet and two of 230 feet each. A vast amount of experiment, calculation, and research was expended on this design, which no doubt answers its purpose, but with an expenditure of material and an unsightliness of effect which seems to have deterred others from following in its wake. The lattice railway bridge over the Mersey at Runcorn, designed by the late Mr. Baker for the London and Northwestern line, is a fine specimen of economy of material and efficiency in the result. Specimens of railway bridges abound on every side, and have developed the capabilities of iron to a wonderful extent. The two largest are probably the viaduct over the St. Lawrence, which consists of 24 spans of 242 feet each, and the more recent one over the Tay at Dundee. The latter is the most remarkable specimen of iron-bridge building which has yet been constructed. It is two miles in length, consisting of 82 spans of various dimensions, 11 being 245 feet between the supports. The construction comprises plate, bowstring and lattice girders in wrought iron, with cast-iron columns and piers in combination with brickwork and masonry. These are, however, to be surpassed in boldness of design by that projected over the Firth of Forth, the designs for which are not yet published.

The facilities of iron, especially wrought iron, for all engineering constructions are more and more appreciated year by year, but with some few exceptions there is a great defect runs through them all in the absence of anything of æsthetic taste in the designs. The ancient motto for building was, "Strength, commodity, beauty." The first two have been attended to almost to the entire neglect of the third. "This," says J. A. Picton, G. S. A., of Liverpool, "I cannot help thinking is a great mistake. The grand engineering works with which the surface of our country is studded should have a dignified and noble aspect. They should minister to the sense of beauty and fitness as well as to that of strength and power; but too frequently the reverse is the case. I will refer to an instance or two. The railway viaducts built by Brunel over the rivers at Chepstow and Saltash are grand specimens of constructive skill, but their aspect is repulsive in the extreme. Let anyone compare London bridge, with the graceful curves of its arches and its simple, yet elegant design, with the iron bridge of Blackfriars, or, still worse, with the railway bridges crossing the Thames; the contrast will be found painful in the extreme. The railway bridge at Runcorn, by Mr. Baker, with its light iron lattice-work and the sweeping lines of the viaducts on each side, is a fine and noble structure. Telford's suspension bridges at Conway and the Menai are charming in this outline and fairy-like in their construction, while their neighbors, the tubular bridges, are the very incarnation of ugliness. This is a defect not inherent in the material, for iron readily lends itself to any shape of beauty. It rather arises from contempt or inadvertence, looking at strength and power as the only elements required."

The Severn Bridge.

The bridge across the river Severn is now completed, the foundation stone having been laid on June 3d, 1874.

The bridge is on the howstring principle, and consists of the following spans: One of 134 feet, two of 327 feet, five of 171 feet, thirteen of 134 feet, and one—including a swing bridge over the Gloucester and Berkeley canal—of 196 feet, making 22 in all. The two spans of 327 feet are across the navigable part of the Severn, and in ordinary ebbing tides afford a headway of 70 feet above high-water mark. In the other cases the headway varies according to the gradient of the bridge—1 in 140. The piers, moreover, vary according to the weight they have to carry. Those bearing the wider spans consist of four cylinders, each of which is 10 feet in diameter from the foundation to low-water level, and 7 feet to the top of the pier, and upon which the girders take their bearings. The piers of the five 171 feet spans consist of two cylinders only, each nine feet in diameter to low-water mark, and from thence seven feet. The width of the river is 1,186 yards, and the entire length of the bridge, inclusive of the viaduct on the Forest shore, and the swing bridge across the canal, is 1,387 yards. It has been constructed for a single line only, although the railways, including the tunnel, have been made for a double line of rails. The total length of railway from Lydney, where the line commences, to Sharpness is about five miles. The superstructure of the bridge consists of howstring girders resting on iron columns, and to allow of vessels passing up the canal the structure terminates on the Sharpness side with a swing bridge 500 tons in weight and about 200 feet in length. It has a double opening, and rests upon a circular tower of masonry. One of the openings of the swing bridge is across the canal, and the other over the adjoining shore of the river. The engine and machinery for turning

the bridge are so arranged that there shall always be a reserve boiler, engine and machinery, to provide for repairs or in case of a breakdown. The locking is effected by iron wedges driven by steam, lifting the bridge, and causing it to take a solid bearing on the piers. The viaduct on the Lydney side of 12 arches 70 feet high, constructed of stone from the forest of Dean, is a fine piece of masonry.

USEFUL INFORMATION.

Misnamed Things.

The misapplication of a name in speaking of the common things of life is the source of many errors. Why things are not correctly named is probably due to the deficiency of our language in descriptive words. The *Journal of Applied Science* has this to say upon this subject:

Why should trade not have a Johnson to classify and correct the mass of inconsistencies that go to make up its nomenclature? We not only tax our brains to invent "fantastic" names for every new fabric, varied, perhaps, only by a thread or a shade from what our grandparents wore a century ago, but there are in use positive misnomers for many staple articles of merchandise. The following imperfect list, culled from sources already at hand, will give a faint idea of them:

Acid (sour), applied in chemistry to a class of bodies to which sourness is only accidental, and by no means a universal characteristic. Thus rock crystals, quartz, flint, etc., are chemical acids, though no particle of acidity belongs to them.

Blacklead does not contain a single particle of lead, being composed of carbon and iron.

Brazilian grass does not come from Brazil, or even grow there; nor is it grass at all. It consists of a palm leaf (*Thrinax argentea*), and is imported chiefly from Cuba.

Burgundy pitch is not pitch, nor is it manufactured in or exported from Burgundy. The resin is a resinous substance prepared from common frankincense, and brought from Hamburg; but by far the greater quantity is a mixture of resin and palm oil.

China, as a name for porcelain, gives rise to the contradictory expressions—British china, Dutch china, Chelsea china, etc., like wooden milestones, iron milestones, brass shoe horns, iron pens, steel pens.

Cuttle bone is not bone at all, but a structure of pure chalk, once embedded loosely in the substance of certain species of cuttle fish. It is enclosed in a membranous sac within the body of the fish, and drops out when the sac is opened, but it has no connection whatever with the sac of the cuttle fish.

Galvanized iron is not galvanized. It is simply iron coated with zinc; and this is done by dipping it in a zinc bath containing muriatic acid.

German silver is not silver at all, nor was the metallic alloy called by that name invented by a German, but has been in use in China time out of mind.

Honey soap contains no honey, nor is honey in any way employed in its manufacture. It is a mixture of palm oil, soap, and olive oil soap, each one part, with three parts of curd soap, or yellow soap, scented.

Japan lacquer contains no lac at all, but is made from the sap of a tree called *Rhus vernicifera*.

Kid gloves are not usually made from kid skins, but of lamb or sheep skins. At present many of them are made of rat skins.

Meerschaum is not petrified "sea foam," as its name implies, but is a composition of silica, magnesia and water.

Mosaic gold has no connection with Moses or the metal gold. It is an alloy of copper and zinc, used in the ancient mosaic or tessellated work.

Mother of pearl is the inner layer of several sorts of shells. It is not the mother of pearl, as its name indicates, but in some cases the matrix of the pearl.

Pen means a feather (Latin, *penna*, a wing). A steel pen is not a very choice expression.

Prussia blue does not come from Prussia, but is the precipitate of the salt of protoxide of iron with prussiate of potassa.

Salid oil is not oil for salid, but oil for cleaning salades, i. e., helmets.

Salt is not salt at all, and has long been excluded from the class of bodies denominated "salts."

Sealing wax is not wax at all, nor does it contain a single particle of wax. It is made of shellac, Venice turpentine, and cinnabar. Cinnabar gives it a deep red color, and the turpentine renders the shellac soft and less brittle.

Sperm oil properly means "seed oil" (Latin, *sperma*, seed), from the notion that it was *spermaceti* (the sperm or melt of a whale). The sperm whale is the whale that gives the "seed oil," which is taken chiefly, but not wholly, from the head.

Whalchone is not hone at all, nor does it possess any of the properties of hone. It is a substance attached to the upper jaw of the whale, and serves to strain the water which the creature takes up in large mouthfuls.

Rhinoceros horn is not horn at all, but a kind of matted or compact hair, and is only like a horn from being a protuberance on the animal's head.

HARDENER GLASS.—M. de Luynes has recently communicated to the French Society of Encouragement, in the name of M. de Labastie, further information on the progress which the industry in hardened or tempered glass has recently been making. He showed to the meeting numerous specimens, which presented the most varied and accurate forms. There were tubes for lamps, both gas and oil, goblets of various forms, mortars and pestles, etc. As to the latter, M. de Luynes reminded the Society how frequently accidents happened with them; the least falls break them, whereas with hardened glass they stand any amount of hard usage. He also showed capsules for pharmacy and chemistry, of all sizes and shapes, plates of glass, crystal and enamel, coffee and tea-cups in white enamel. He finished by making a striking experiment. Ordinary glasses were placed in a basket with drinking-glasses of the same shape in hardened glass; after several shakings, the ordinary glasses were all broken, while all the hardened glasses were intact. Thus it would seem that all the difficulties of the question have been solved. But, what is more important, the processes of manufacture have been simplified and combined with the ordinary operations of glass-blowing, so as considerably to diminish the expense and give more regular forms and more perfect execution. Objects made with the liquid material, when they are still red, are thrown directly into the tempering bath, and are not again heated to the melting point, as at first, which often causes a change in their form. Bottles, drinking-glasses, lamp-glasses, and other concave objects containing air, are received on a curved tube—a sort of syphon—which, at the moment of immersion, allows the air to escape, while the liquid enters the cavity without difficulty. All these improvements have been adopted at the glass works of Choisy-le-Roi, and it is confidently expected that in a very short time objects in hardened glass will be quite as cheap as those made in the ordinary way.

IMITATION OAK FLOORS.—A simple and beautiful method of giving to floors an almost perfect appearance of oak or walnut has come into vogue in London, and is largely increasing in popularity. The method consists in putting one ounce Vandyke brown in oil, three ounces pearl ash, and two drachms dragon's blood into an earthenware pan or large pitcher; on this mixture is poured one quart holling water, and the whole stirred with a piece of wood. The article may be used hot or cold. The boards are first smoothed with a plane and sand-papered, the cracks being filled with plaster of Paris, and then a stiff brush is dipped into the stain, and with this it is well rubbed in—the brush being rubbed lengthwise of the boards. Only a small piece is prepared at a time. By rubbing in one place more than another, an appearance of oak or walnut is more apparent. When quite dry, the boards are sized with glue size, made by holling glue in water and brushing it in the boards hot, and on this becoming dry, the boards are papered smooth and varnished with brown hard varnish, or with oak varnish—the first-named kind wearing better, and drying quicker if previously thinned with a little French polish, a smooth brush to be employed in applying it to the boards.

RAG PACKING FOR VALVES, BEARING SPRINGS, ETC.—This is made principally from the useless cuttings in the manufacture of India-rubber coats, when the gum is run or spread on calico foundations. Proportions as follows: Grind together useless scraps, 35 lbs.; black-lead, 18 lbs.; Java gum, 16 lbs.; yellow sulphur, 1 lb.

GOOD HEALTH.

Cholera in Japan.

Dr. D. B. Simmons, of Yokohama, writes as follows to the National Board of Health in regard to the present epidemic in Japan, under date of September 3d, 1879:

The epidemic of cholera has assumed considerable proportions, having reached 100,000 cases, with a mortality of about 50%. The disease was imported from China during the summer of 1877, and in that year the number of cases was between 14,000, and 15,000, with an average mortality of about 50%. Though nearly dying out in the winter, it reappeared the next year, but the cases were comparatively few. It lingered principally in Osaka. This year it began quite early in the season, and Hioga has been the principal center from which the disease has spread over the whole empire. Within the last two months it has rapidly increased until it has reached the figures above given. Strenuous efforts have been made by the government to stop its progress in every direction. A coast quarantine was established between here and Kobe, and Osaka; but unfortunately, the disease was brought here by two steamers just before this measure was put in force. There is positive evidence that if these two steamers had not arrived the disease would have at least been delayed more than a month. Hospitals are established in every part of the empire, and sanitary measures in accordance with modern scientific ideas are everywhere being carried out. Great trouble arises from the want of a proper supply of cheap disinfectants. Carbolic acid ranges from \$2 to \$2.50 per pound. I have strongly advised the use of sulphurous acid, which was largely employed at Yokohama, in

1877, under my instructions, and, I am sure, with good results.

The type of the disease is rather peculiar, so that some foreign physicians denied for some time that it was cholera. Vomiting and rice water evacuations were not seen in more than half the cases, if in so many; the stools were often yellow, or green and slimy. I have seen a large number of cases, but most of them have passed into the stage of collapse. The diarrhea in the fatal cases is not often severe, but suppression of urine comes on early, followed by death in from 8 to 24 hours. I have used jehorandi and thilocarpin in many cases, and have brought on the secretion of urine frequently when the cases were not too far advanced. The reaction, when produced by these drugs, seemed less likely to be followed by secondary fever than when stimulants were used.

Is Alum Poisonous?

This question has caused a good deal of discussion. Alum is used by many bakers to whiten their bread, enabling them to use an inferior flour. It is more extensively employed as a cheap substitute for cream of tartar, in the manufacture of baking powders. It has not been considered immediately dangerous; although if continued it induces dyspepsia and obstinate constipation. But the fact that many cases of poisoning have occurred from baking powders which contained alum, puts the question in a more serious aspect, and prudent people will exercise caution in selection of baking powders.

Under what conditions, then, does this substance—formerly used only for mechanical or medicinal purposes—become poisonous? They are certainly obscure, and at present we can only surmise what they may be. We suspect that the cause exists in the individual poisoned; some peculiarity of the constitution producing a morbid change in the secretions of the stomach, with which the alum combines and forms an active poison; or the secretions may be healthy but in unusual proportions, and that these less or greater proportions, in combination with the alum, constitute a poison.

For example: Two parts of mercury and two parts of chlorine form calomel, which is not poisonous; but change the proportions to one part of mercury and two parts of chlorine, and we get corrosive sublimate, which is a deadly poison.

Then, again, we know nothing of the causes of constitutional peculiarities. Why is it that one person can eat all kinds of green fruit and vegetables with impunity, while the same course might cost another individual his life? One person can handle poison ivy and sumac without being in the least affected, another is poisoned if he approaches to within 10 feet of them. Out of a family residing in a malarial district, some of its members will suffer half the year with fever and ague, while the others will enjoy excellent health during the entire year. Foods that are wholesome to some persons are actually poisonous to others. This is especially true of some kinds of fish. There is no safety in taking alum into the stomach, as it is shown to be always injurious, and often dangerous. Baking powders properly compounded, and containing pure cream of tartar instead of alum, are more convenient than yeast; and bread and pastry made with them are just as wholesome, and far more palatable.—*Hall's Journal of Health.*

TOXIC EFFECTS OF TEA.—Dr. W. J. Morton, in a paper upon the above subject, read before the recent annual meeting of the American Neurological Association held in New York, arrives at the following conclusions in relation to the use of tea: 1st. That with it, as with any other potent drug, there was a proper and improper use of it. 2d. That in moderation it was a mild and pleasant stimulant, followed by no harmful reaction. 3d. Its continued and immoderate use led to a very serious group of symptoms, such as headache, vertigo, ringing in the ears, tremulousness, "nervousness," exhaustion of mind and body, with disinclination to mental and physical exertion, increased and irregular action of the heart, and dyspepsia. 4th. The mental symptoms were not to be attributed to dyspepsia. 5th. It diminished the amount of urine, and retarded the metamorphosis of tissue. 6th. Many of the symptoms of immoderate tea-drinking were such as might occur without a suspicion of the real cause.

ENEMIES OF HUMAN LIFE.—An English paper, *Capital and Labor*, thinks that, while excessive labor, exposure to wet and cold, deprivation of sufficient quantities of necessary and wholesome food, habitual bad lodgings, sloth and intemperance, are all deadly enemies to human life, none of them are so bad as violent and ungoverned passions. Men and women have survived all the former, says the writer, and at last reached an extreme old age, but it may be safely doubted whether a single instance can be found of a man of violent and irascible temper, habitually subject to storms of ungovernable passion, who has arrived at a very advanced period of life. It is, therefore, a matter of the highest importance to every one desirous of preserving "a sound mind in a sound body," to have a special care amid all the vicissitudes and trials of life, to maintain a quiet possession of this own spirit.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A Heavy Mining Blast; Where to Explore for Minerals; A Gas Engine, 321. The Week; California Mining Interests; Gold and Silver Product; A Swindling Land Scheme; The Black Sand Bonanza; Continental Pacific Railroad, 323. The Supreme Court and Mining Debris; The Mount Jefferson Mine; Result of Economy in Mining, 329. Notices of Recent Patents, 333.
ILLUSTRATIONS.—The New Otto Silent Gas Machine, 321. Finger Rock, Echo Canyon, Utah, 329.
CORRESPONDENCE.—Nevada Mines—Emeralds County; Coos Bay, 322.
MECHANICAL PROGRESS.—Air Compressor with Water Pistons; The "Dynamograph" Car; Saw Sharpening Machine; The Anacapa Table-Lamp; Transfer Lathe; Plume for Cord Wood; An Octopole Printing Telegraph, 323.
SCIENTIFIC PROGRESS.—A New People; Printing and Lithographic Lugs; New Pocket Lens; Theory of the Telephone; Chlorine, Bromine and Iodine; Carbides from Petroleum; A New Base, 323.
MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards. Notices of Assessments, Meetings and Dividends, 324-325.
MINING SUMMARY.—From the various counties of California, Nevada, Idaho, Montana, New Mexico, Arizona, Oregon and Washington, 325-332.
THE ENGINEER.—Iron in Engineering; The Severn Bridge, 327.
USEFUL INFORMATION.—Misnamed Things; Hardened Glass; Imitation Oak Floors; Rag Packing for Valves; Bearing Springs, Etc., 327.

Assessment Notice—Cataract and Wide West H. O. M. Co.

The Week.

The event of the week has been the decision of the Supreme Court in the mining debris suit, a decision virtually in favor of the miners, and removing from hydraulic mining interests a cloud which threatened total extinction. To the mining community all other news is as nothing to this in importance, and on every hand we bear evidences of rejoicing among the miners. Although not reaching the merits of the case as to whether the miners have a right to run the debris into the streams and thus pollute the water so as to injure the plaintiff, this decision is regarded as virtually deciding the whole case in favor of the miners, as it will be impossible to prove the amount of damage that each mining company commits, or that the act of any one of them is sufficient to do the injury complained of. Besides, if the plaintiff in the case has to commence separate suits against all the parties, the process will be so expensive and slow that there can scarcely be any end to it. There is not the slightest doubt but that the miners will, in the future, as in the past, pay for direct damages in dumping their tailing on to the land of others, and this without any suits. They have in many instances paid more than market price for lands to be utilized as dumps. We believe that if both parties meet in a spirit of mutual concession and good will, a satisfactory settlement of this subject of mining debris will be reached without continual litigation, which is expensive and annoying to both parties.

In this city half dollars are quoted at par; trade dollars, 95 buying, 96½ selling; Mexican dollars 96 buying, 96½ selling.

A DISPATCH from Cape Town announces that hostilities between the Boers and Colonial authorities have been resumed.

The Piutes are in war paint at Carson, Nev., vowing vengeance against the Washoes.

California Mining Interests.

The Eastern press, with few exceptions, seems determined to ignore California in every allusion made to the mining future of the West. Whether the cause is founded upon the notion that California mines are worked out, or that Eastern capital has become so largely "etuck," so to speak, in the carbonate fields, is immaterial to the fact that our State is in many respects as utterly disregarded as if it did not exist. The golden exaggerations of some other States and Territories, when touched with the expert finger of the statistician, fall so far below even mediocrity that it is a surprise that such fabulous accounts should ever have been credited. We ought not to say that the credibility, or rather gullibility, of the Eastern press should be so easily imposed upon, for the reason that it is a trite saying that "Distance lends enchantment to the view." The inaccessibility of the mines in the comparatively new regions of the West affords a foundation for the truthfulness of the accounts of rich discoveries proportionate to the difficulty of arriving at the exact truth. The wonderful accounts of Sinbad the Sailor were very ordinary ones when compared with those of Munchausen. No person had been present who could dispute the relations of either, and so they were regarded as solemn truth by their hearers because they were indisputable. For the same reason, many of the Eastern press are in possession of the truth *a la* Munchausen. California is now quite accessible, and the charm of adventure and mystery attending the prospecting for the precious metals has dispelled the charm and diminished the claim of the marvelous, which has moved to other regions practically unexplored.

It is this spirit which moves our Eastern exchanges to lay much stress upon "Colorado, Arizona and New Mexico as without doubt the field of the future in mining enterprise, while Utah and Montana may continue to develop remarkably in respect to mineral resources."

We are unwilling to utter one word against the prospects of any of these States and Territories. The merits of every one will, however, become more manifest at some future day, when the reality of production is assumed as the basis of calculations, and not the number of mines offered for sale, and the merits of which are depicted in the glowing colors which a mine owner, anxious to sell, knows so well how to exhibit. The point that we contend for is this: That while it is so easy to know of the future of California, and that future is of such great promise, it is a mark of something else besides mere ignorance which will coolly pass her by.

The early prospectors in this State, led by the scent of gold, eagerly followed up the gold-bearing streams, imagining wisely that the source from which the placer gold came, must be enormously rich. This search led to the discovery of the Comstock lode, which absorbed the interest of the whole coast, and caused the capital that was ready for the development of our quartz veins, to flow into Nevada. Then followed the wild orgies of stock speculation, which has practically continued more or less, down to the late general depression in Comstock, which has had the effect of giving an impetus to the development of the quartz veins of California, and this too, we may say, for the first time. In all these previous years the old mining districts along the western slope of the Sierra Nevada remained dead. Some of them have been buried up a hundred feet and more beneath the debris of nature's denudations. Now these old and abandoned mines, and incipient developments of quartz veins are being rehabilitated, and are proving their stability as paying investments. There are no astounding fortunes to be made, and all the better for that. The remuneration will be endowed with greater stability and be better appreciated. A steady stream of gold has always flowed into the markets of the world from California, which is essentially the reservoir of the gold product for the country, nay, of the world. Our placers alone, fed from innumerable and yet untouched gold-bearing rocks, have yielded more than three times as much gold and silver as all the gold and silver mines in the United States, and this quantity is only a drop in the bucket when compared with the gold existing in the sources of these placers. The statistics of the United States Mint demonstrate the fact that California has no competitor in gold production, and the few quartz mines which have been and are now in operation, give a faint glimpse of future capabilities. The Black Bear quartz mine has paid 68 dividends, amounting to \$336,000, without a single assessment on its stock. Bodie has paid over \$1,000,000, with but \$20,000 levied in assessments. The Hite mine, of Mariposa, has paid \$1,370,000, and the Idaho mine, at Grase Valley, \$2,650,000 in 121 dividends straight along. Many of our best quartz mines are not known in stock circles—such as the Black Bear and Sheep Ranch, in Calaveras. It needs but capital and enterprise to develop hundreds more of such mines in the counties of Nevada, Plumas, Butte, Placer, El Dorado, Amador, Calaveras, Tuolumne and Mariposa. One of the best mines ever discovered is the old Hayward quartz mine, of Amador county. It was worked before the Comstock was heard of. It did not cost \$150,000 to develop it in a paying

basis. It has paid more than \$10,000,000 above all operating expenses, and is still a good mine. The carnival of exaggeration will soon be over, and the capital which has been so long diverted from their proper channels, to-wit: the development of the gold-bearing veins of California, is beginning to return with satisfactory returns.

Gold and Silver Product.

Director Burchard, of the United States Mint, in his annual report, just completed, estimates the total production of precious metals during the year 1879 as follows:

	Gold.	Silver.
California.....	\$17,600,000	\$2,400,000
Nevada.....	9,000,000	13,500,000
Colorado.....	3,225,000	11,700,000
Utah.....	575,000	6,250,000
Montana.....	2,500,000	2,225,000
Arizona.....	800,000	3,350,000
Dakota.....	2,420,000	10,000
Idaho.....	1,200,000	650,000
Oregon.....	1,150,000	20,000
New Mexico.....	125,000	600,000
Michigan.....		780,000
Other domestic sources.....	305,000	67,000
Grand total for U.S. and Ter.	\$38,900,000	\$40,812,000

It will be seen by the estimate that in the grand total silver is in excess of gold by about two millions of dollars, it having gradually approached an equality of production for the past years. The continued output of silver from Colorado, Nevada and Utah, which is promised by the reports from mining localities, may possibly, in a few years, place silver as far in advance of gold in annual yield as gold has exceeded silver in the past.

The consequences might possibly result in the cheapening of silver and its exclusion from the market as a medium of exchange, unless the supply so far exceeding the demand should cause a partial cessation of the output. From the present report it appears that California maintains her prestige as a gold-producing State, furnishing, in fact, nearly one-half of the entire gold product. This production of gold occurred during a dull year, when active mining could not be considered at its highest point, and from indications of increasing developments it may be said that the amount will be larger for the next year.

In any event California seems to stand in the position of an adjuster of the precious metal equilibrium. Silver may be considerably in excess of gold in the supply, without very much depreciating in value, because it is a commoner metal, and in more general use. But the supply of gold should not be allowed to fall below the proper ratio, for the reason that a diminution of values would be likely to occur. Experience in the past has shown this to be true, and aside from experience, the law of demand and supply would demonstrate it.

The enormous supply of silver expected from Colorado and other points, will, in all probability, be more than counterbalanced by the supply of gold from California and other specially gold-producing regions.

A Swindling Land Scheme.

A dispatch from Denver brings the information that Sidney A. Grant and A. F. Wilson were arrested in Denver a few days since for conducting a fraudulent scheme through the mails under the name of the "Denver Land Company." We refer to our advertising columns this week for full particulars concerning the scheme. It will be seen that glowing descriptions are given by the advertisers of the desirability of certain lands which are represented to be in the city of Denver. The truth of the matter as it comes in the dispatches is as follows: "The scheme was planned in Cincinnati. Stereotype plates were prepared, and have already been inserted in over 800 first-class newspapers and periodicals in the Northern, Eastern and Middle States. Grant came to Denver to secure land for the purpose, and bought nearly a thousand acres in the sandhills, 40 miles north of Denver, in another county, which was platted and recorded as North Denver. Although known here but eight days, a perfect avalanche of mail was coming for S. A. Grant and the Denver Land Company. The fraud was denounced by the local newspapers, and bitterly condemned by the citizens. The postmaster reported to the Department, and last night received orders to deliver no registered letters and pay no money-orders to Grant. The arrest was made by Special Agent H. Hall. Special Agent Furay is also here, and asks the Department to order the withholding of ordinary letters."

The movers of this swindle were promptly arrested by the Government officers, and being without bail, they were jailed for trial. The result of the swindle affords a good illustration of the "hitter bitten."

The official vote of Pennsylvania for State Treasurer is as follows: Republican, 280,153; Democrat, 221,815; Greenback, 27,207; Prohibition, 3,219.

All the hostile Ute chiefs are gathered at the Los Pinos Agency, except Jack, who positively refuses to come in and confer with the Commission.

A FORMIDABLE revolution is in progress at Ohiuabna, Mexico, and new difficulties have arisen in Yucatan.

The Black Sand Bonanza.

The fact that Prof. Edison has an agent in the mining region of this coast, looking into the waste of gold in the present mode of hydraulic mining, seems to justify the statements going the round of our exchanges, that the Professor has discovered a method of saving the gold thus thrown away, at the same time and in the same manner that he proposed to save the platinum. He went still further and authorized McLaughlin (Edison's agent) to make contracts with the principal mining companies with a view of building the necessary works at this city for putting his plan in operation. This is what Major McLaughlin says is desired by Edison at the hands of our miners, and what he proposes to render in return. He desires the latter to make contracts giving him the exclusive right to put in at his own expense a system of undercurrents and end flumes (in addition to whatever flumes and undercurrents they may see fit to use) by which to save the black sand and whatever platinum it may contain. In return for this privilege, he will guarantee to give the miners one-half the gold product of the black sand, free of expense to them. He does not desire to save anything that the miners themselves can save.

The *Oroville Mercury* says: "A fairer proposition than this we cannot conceive of. Heretofore the miners have realized nothing from either the black sand or platinum, but should this offer be accepted, and we have no doubt but it will, the yield of their claims will henceforth be increased from 50% to 100%, according to the quality of the sand. As Edison is the only person knowing how to save the valuable metal now going to waste, he is the only one who can offer such generous terms without sacrificing his own resources—and it is reasonable to suppose that he knows what he is about. The reduction works will cost something like \$50,000, and furnish employment to 50 men. They will be in operation, providing the necessary contracts can be made, by the middle of February or first of March. While the works will prove a great value to this community especially, the discovery is destined to work a revolution in the mining industry of the State, and will eventually cause an era of prosperity in comparison to which the days of '49 will appear insignificant and unworthy of notice. In conclusion we would urge upon our miners the advisability of availing themselves of Mr. Edison's proffers at an early day, as there will undoubtedly be an avalanche of applications as soon as the fact becomes noised abroad."

Continental Pacific Railroad.

We acknowledge the receipt of a pamphlet entitled *La Grandiosa Obra de todos los Siglos, El Ferrocarril Universal*, and also a copy of *El Comercio Periodico Mercantil*, both of which are devoted to a *Gran Proyecto Americano*—"a Continental Pacific railroad," which is to have its termini at San Francisco and Montevideo, crossing all the Central and South American republics. It is to be 6,000 miles long, and will cost the small sum of 325,880,000 "strong" dollars (*pesos fuertes*). The freight and passenger tariff has already been established. A branch line is to be built to Behring's straits, in order to explore the North Pole, thence passengers will be carried over a 13-mile bridge into Asia to Peking, Persia and across the Sahara desert. The object of this "grand continental railroad" is to enable the population of the earth to travel about and civilize the barbarous portions of the community, as also to solve many scientific and mechanical problems. A board of directors is to be established in every country through which the line passes, all, however, subject to the *Directorio General*, who is to locate in San Francisco. Any person can become a *Directorio General* for 25 shares of the stock, while a common to ordinary *Directorio* can get the position for 15 shares of stock. The stock is fixed at \$500 per share, a moderate amount when the enormous advantages of this railway are considered. Although the timetable has been arranged, and the freight and passenger tariff fixed at extremely low rates, tickets will not be issued nor freight received until the road is built. The sum of \$325,880,000 being the only drawback to the speedy completion of the road, the railroad from Chicago to Patagonia must now take a back seat. The pamphlet before alluded to, which by the way is written by a gentleman entitled Juan B. Bobbio, says that the nine wonders of the world are a bagatelle to this railroad, which will likewise afford a profound and illustrated study, meditation and observation for the mathematician, politician and financier. We believe it, and if it is going to remove all the miseries of humanity, as Mr. Bobbio says, we are in favor of it provided we can be the *Directorio General*.

The General Committee of Church Extension of the Methodist Church are holding their annual meeting at Philadelphia.

FERNANDO C. BEAMAN has been appointed by the Governor of Michigan United States Senator, vice Chandler, deceased.

The Supreme Court and Mining Debris.

A Decision in Favor of the Miners.

On the 17th inst., the Supreme Court of California sustained the objections made to the complaint by the defendants in the case of *Keyes vs. Little York Gold Washing Co.*, because of misjoinder of parties, and that the judgment and order were accordingly reversed, and the court below would be directed to sustain the demurrer. As indicating the ruling to be final and irrevocable, it was added that the remittitur would issue forthwith. This dissolves the injunction against the miners, throws the case out of court, and, so far as the present suit is concerned, ends it.

The opinion of the court is substantially as follows: "The complaint sets forth that the plaintiff is the owner of certain described premises known as the bottom lands, situated in the valley upon the banks of Bear river, about ten miles from where that stream debouches into the Sacramento valley, and midway between that point and the mouth of the river; that the defendants are miners severally engaged in hydraulic mining at points high up on Bear river and its tributaries—the several mining properties of the defendants lying within a radius of seven miles upon the hill tops adjacent to the river, and being severally wrought and carried on by the respective defendants, and that the several dumps used by the defendants respectively in their mining pursuits are some of them in the bed of the river, others in the beds of its tributaries, and yet others in the beds of steep ravines and gulches, immediately contiguous to and leading into the bed of the river or its tributaries; that the tailings of the several mining claims deposited on these dumps are swept down the river by the force of the current until they reach the lands of the plaintiff below, upon which they are deposited, and which they cover so as to destroy the value of said lands. The prayer is that an injunction issue enjoining the defendants from depositing the tailings and debris of their several mining claims so that they reach the channels of the river, etc.

"The defendants appeared to the action and filed a demurrer to the complaint upon several grounds—and among the others upon the ground that there is a misjoinder of parties defendant, in that it did not appear by the complaint that the defendants jointly committed any of the acts complained of, or are acting therein in concert or by collusion with each other, but that, on the contrary, it did appear by the complaint that the defendants had no interests in common in the subject-matter of the suit, but were acting severally, and without any joinder or co-operation on the part of the defendants, or any of them. The demurrer was overruled by the court below, and the propriety of its action in that respect is brought in question by this appeal.

"An injunction is granted when the relief sought consists, wholly or in part, of restraining the commission or continuance of acts being done or threatened, or when the commission or continuance of acts during litigation, will produce irreparable injury or render a judgment in plaintiff's favor ineffectual. (Code of Civil Procedure, Section 526.) The injunction ordered at the final hearing by the court below was not ancillary to any other provision of the decree, nor added to render some other final order more effective. It was the only decree sought by plaintiff, and is the very most that the allegations of his bill would have entitled him to, had the defendants been charged with co-operation, and a common design in doing that which each threatened. There are indeed recitals in the complaint alleging plaintiff to have already sustained damages, but no relief is sought upon them as allegations constituting the basis for a decree. They are rather in the nature of statements of evidence tending to sustain the averment that like damages will occur in the future unless defendants are restrained. In the face of a demurrer for misjoinder (even had damages for past injuries been demanded in this case) no judgment for damages could have been rendered against the defendants jointly, because they are charged each to have committed a tort severally; and several judgments for damages could not have been rendered against each of the defendants in the same action, for such judgments would have demonstrated the misjoinder. No damages are claimed in the prayer for judgment or in the points of counsel.

"The wrong complained of is that each of the defendants, acting for himself and not in collusion or combination with any other, threatens to continue to deposit the tailings from the working of his mine in such position, on or adjacent to his own premises, as that, from natural causes, they will flow down or be forced down upon the plaintiff's farm.

"If a nuisance was created by the exposure of the dumps to the action of the waters of Bear river and its tributaries, a nuisance was com-

mitted by each of defendants when he—disconnected from the others—made or threatened such deposit; or, if it be said that the matter of the reasonable use of the stream can enter into the inquiry, there could be no nuisance by any of the defendants who had made only a reasonable use.

"In either view of the case there is a misjoinder of parties defendant. The bare statement would seem to prove the proposition, since the very essence of the objection of misjoinder of a defendant with others is that he is not connected with or affected by the single cause of action, if there is but one, or that he is not connected with or affected by one or more of several separate and distinct causes of action, if several are alleged. If any one of these defendants was liable to be enjoined he could have been enjoined in a separate suit, the subject-matter of such suit being the alleged threatened wrong. If any one of the defendants is not liable to be enjoined in a separate suit he cannot be made liable in an action like the present; for there is no principle of equity which would make a man responsible for a wrong which he has neither done nor threatened, merely by joining him with other defendants who may independently have threatened a similar wrong."

In most of the cases cited in support of the complaint and against the objections urged in the demurrer, the main point was either that the plaintiff had an exclusive right against which the defendants were asserting adverse rights, as in the case of an infringement of patent, or that there was a privity between the defendants, a combination, as it were, which does not exist in the present case so far as the allegations in the complaint are concerned.

The court regarded the rule at law where an action for a tort is brought against several co-defendants, it is essential that the wrong com-

mitted be the nuisance. The miners have always paid, without suits, damages resulting from dumping their tailings directly on to another's land, and have bought thousands of acres for dumps.

The decision has also had the effect of ending the proceedings instituted by the city of Marysville against the hydraulic miners of Sierra, Plumas and Nevada counties to enjoin them from further sending debris into the Yuba and Feather rivers and their tributaries.

The Mount Jefferson Mine.

We learn from a gentleman just arrived from Tuolumne county that the chlorination works at the Mount Jefferson mine have been rebuilt and are once more in successful operation. These works were permitted to fall into disuse and decay some years ago, when for lack of pumping facilities the mine filled with water and work on it ceased. Latterly, however, the company has been reorganized and new pumping machinery erected. After some time spent in trying to make the mine pay on the free gold in the ore, the managers concluded very wisely to repair these works and continue operations on the old plan of concentration and chlorination, so successfully followed in the palmy days.

The roasting furnace here, which is the principal feature for reduction by this process, has three hearths or compartments, in steps about two feet high and connected by openings through which the heat passes successively from the fireplace. The upper or back chamber most distant from the fire is of course the coolest. Into this the raw charge is introduced, where it remains for some eight hours, when it is passed to the next compartment and so on through the series, the mass being kept in mo-

Result of Economy in Mining.

The Ferguson mine, in Mariposa county, continues to open out in a way that must be very gratifying to the owners, and fully justifies the patient and business-like method of working to which they have steadily adhered. Instead of rushing after each ton of ore as soon as it could be got out, no matter how disadvantageously, and therefore expensively, their first attention has been given to opening out fairly the large bodies of ore standing in the mine, putting the bulk of the proceeds back into the mine in pushing forward the developments, and contenting themselves meanwhile with a moderate margin over running expenses. The result is that they now have one of the best developed mines—perhaps the best, not excepting the adjoining Hite mine—in the county, with reserves of good pay ore enough for years of very profitable working.

In the main tunnel, which has been drifted on the fissure for 1,500 feet right into the mountain, three distinct bodies of valuable ore have been developed. Two shafts have been sunk on these chutes, one 170 feet and the other 200 feet deep, and from the bottom of the latter a level has been run north and south over 600 feet, the whole distance on good milling ore from one to three feet thick, though at one or two points it becomes narrower, and for a short distance is hardly wide enough to extract profitably. At the south end of this level the vein is three feet wide, and the north end two feet; the extent of the ore body in each direction has yet to be proved. Below this bottom level a winze has been sunk nearly 40 feet deep. In it the vein averages over two feet wide, and it shows old freely. Some exceedingly rich rock has been found in the mine, but the average ore yields from \$12 to \$30 per ton in the mill. The whole cost of mining and milling does not exceed \$7 per ton, as the facilities for economical working are exceptionally good. The Merced river gives a constant and practically unlimited power, free of all cost; and when the milling power is increased, as it will shortly have to be, the cost per ton will be still further reduced. The lowest point in the mine is over 700 feet below where the vein was first discovered and worked, and the present indications justify the expectation that the vein may be found to extend 700 feet further, or indeed to an indefinite depth.

If the same care, pluck and patience were exercised by parties engaged in mining on this coast, as the owners of the Ferguson mine have displayed, equally good results would, in many cases, be obtained; and though all mines cannot be expected to open up such extensive bodies of pay ore, there are series of mines, now idle or running unprofitably, that could be made to yield very satisfactory returns to their owners. There are few enterprises that offer so good a field for the safe and profitable investment of capital as does gold mining in California, if only it be prosecuted with the same prudence, vigor and economy as are essential in any other kind of business.

BORAX WORKS.—On the line between Inyo and Kern counties, California, is located Borax lake. The works of Searles & Co. are located here, and are turning out regularly, says the *Independent*, fifty tons of refined borax per month, being an average of just one ton each for the men employed, all told. The works are doubtless the most perfect in plan, appointments, extent and condition of any in the world, and have at hand the most extensive and inexhaustible supply of the crude material from which the merchantable borax is manufactured. The works have an actual capacity of 600 tons per month, but owing to the present limited demands of the world's market, are run to but one-sixth of their capacity, as above stated. The locality, its surroundings, products, modes, capabilities, geological, mineralogical, chemical and, last but not least, its agricultural peculiarities together constitute this the most interesting field for the merely curious as well as the scientific to be found in this whole country.

NAVIGATION on the canals in New York will be closed Dec. 6th.

Caution!

In the absence of the Senior proprietor, the advertisement on page 330 of this issue was inserted. Telegrams from Denver assure us that we have been imposed upon, that the scheme is an unmitigated fraud, and all readers are hereby cautioned against patronizing the Denver Land Company.

FINGER ROCK, ECHO CANYON, UTAH.

plained of be joint, as well understood and undisputed, and remarked if there are any exceptions in equity they have not been called to its attention. "We are convinced that none can be found which will authorize the joinder of defendants attempted in the proceeding before us."

We are moved to remark that while the merits of the case have not been passed upon as desired by the plaintiffs, yet the decision was not upon a mere technicality. The "misjoinder of parties" has more to do with the merits than would be supposed at first blush, since it appears to affect the right of the plaintiff to bring any action. The proceeding was an attack upon the whole body of miners, and an attempt to stop their further deposition of debris at one and the same stroke. This, the court says, cannot be done. Perhaps it is a very fortunate thing that it does so hold, and here we argue for the farmer as well as for the miner, for once admit that an entire community must depend upon the good or ill nature of a single individual, and a doctrine of absolutism is established to destroy which was the mainspring of the War of the Revolution.

In our judgment an amicable settlement would accomplish better results than law suits.

The hydraulic miners have not assumed an aggressive position, but have simply defended what they claim as their rights. They bought their lands at the double price of \$2.50 per acre from the United States Government, and the act of 1866 gave them certain rights of way for canals and ditches, which act was subsequently codified in the United States laws. The farmers in the suit just decided, commenced action against a number at once, not for damages, but to restrain them perpetually from depositing the tailings and debris of their several claims in the channels, and for suffering the tailings from flowing into the rivers and fouling and polluting them. If this view had held, the miners would have had to shut down entirely. Under the decision cited above, separate actions against each miner may be commenced, but the direct damage must be proven—that the one sued

tion throughout the process by means of stirring with iron hoes. By this means about 1½ tons of sulphurets per day are completely desulphurized. After thorough roasting the pulp is placed in large vats where it is treated with chlorine gas generated by means of salt and sulphuric acid. The gold is thus converted into a chloride, which being soluble in water is leached off into another vessel where it is precipitated with sulphide of iron and collected by decanting or filtration.

The ores from this mine contain a very large proportion of sulphurets of iron, some deposits carrying as much as 15%. These sulphurets, when perfectly clean or free from gangue matter, are worth by fire assay about \$100 per ton; but in roasting for chlorinating it is found much better to have them mixed with a proportion of sand. This has a tendency to prevent matting, and gives the sulphur a better chance to pass off, so that in practical working it is aimed to have them carry about 30% or more of quartz, thus reducing them to about \$60 per ton. Of this gross value about 30% can be saved by the process above described, and as the ore contains on an average about 8% of these sulphurets, a great saving is effected. The amount of ore here reduced is sufficient to keep the chlorination works supplied with sulphurets. Heretofore these have mostly found their way down the creek. It costs by this process about \$12 to extract the gold from a ton of sulphurets, and allowing the liberal sum of \$4 for concentration, the company will be able to save at least \$40 per day.

FINGER ROCK.—Echo canyon, in Utah, contains many remarkable features in the way of rock formation, caused by erosion or the wearing away of the soft soil, leaving hard rocks prominent. These assume fantastic shapes, which have been named according to the resemblance which they are supposed to bear to the object from which they are named. Hence Finger Rock, as in our illustration, Pulpit Rock, Devil's Slide, and numerous others.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY &
CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

**Roasting of Gold and Silver Ores, and the
Extraction of their respective Metals without Quick-
silver.** 1870.

This rare book on the treatment of gold and silver ores
without quicksilver, is liberally illustrated and crammed
full of facts. It gives short and concise descriptions of various
processes and apparatus employed in this country
and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces,
implements and working apparatus.
It is a work of great merit, by an author whose reputation
is unsurpassed in his specialty.

Price, \$2.50 coin, postage free.

**Concentration of Ores (of all kinds), including
the Chlorination Process for Gold-bearing Sulphurets,
Arsenurets, and Gold and Silver Ores generally, with
120 Lithographic Diagrams.** 1867.

This work is unequalled by any other published, embracing
the subjects treated. Its authority is highly esteemed
and regarded by its readers; containing, as it does, much
essential information to the Miner, Metallurgist, and
other professional workers in ores and minerals, which
cannot be found elsewhere in print. It also abounds
throughout with facts and instructions rendered valuable
by being clearly rendered together and in simple or
der. It contains 120 diagrams, illustrating machinery
etc., which alone are of the greatest value. PRICE, \$7.50

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114
pages, for miners and prospectors, by Chas. H. Aaron,
which has been issued by Dewey & Co. Mr. Aaron
has managed to give many useful hints and suggestions,
free from all technicalities, and in such a style as to be
easily comprehended. It is written for the miner, with no
chemical symbols or metallurgical technicalities to confuse
those who are not chemists or metallurgists. The following
summary of the contents of the work will give an
idea of its scope:

Under the heading of the first chapter, "Testing Ores
for Silver," we find paragraphs on ore formation test for
silver, with heat and water, acid or blow pipe. In speak-
ing of testing for a process, the extent and richness of ore
is considered, smelting ores, selecting and working same
ple, appliances for testing, roasting, etc. Under the head
of "Working Ores" the author describes Aaron's process,
has something to say of superheated steam, preparation of
dichloride of copper and protochloride of copper, use of
copper and iron, quantity of chemicals, carbonate of lime,
chloride ores, amalgam, Patchen's process, etc. He also
describes the methods of working roasted ores, treatment
of base metals, stirring, heat of furnace, want of sulphur,
etc. Under the head of "Leaching Processes" are the
titles, Smelting, Mexican process, Chilean process,
Krohnke's process, etc. Under "Pulverizing Machines" are
described the arastra and its construction and operation,
stamp batteries, screens, Crocker's trip-hammer bat-
tery, Paul's pulverizing barrel, Kendall's battery, Noice's
pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a
cheap amalgamator, grinding the ore, directions for
making a barrel, preventing mechanical wear, use of
quicksilver, copper in bars, Freiberg barrel, cheap barrel
trough, barrel on rollers, Aaron's amalgamator, separator,
etc.

He describes an improvised retort, roasting furnace, fur-
nace tools and furnace building. Among the miscella-
neous mention may be found Aaron's leaching apparatus,
with two or three different arrangements, a small mill,
sampling tailings and settling tanks, dichloride of copper,
etc. Mr. Aaron is a practical miner, of long working ex-
perience on this coast.

The book is a serviceable one for miners' and prospec-
tors' use. Price, post free, \$2.00. Address Dewey & Co.,
MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San
Francisco.

Grimshaw on Saws.

History, Development and Action, Classification and Com-
parison, Manufacture, Care, and Use of Saws of all kinds.
8vo. Illustrated. By ROBERT GRIMSHAW.

This thorough little work, impartially written in a clear,
simple and practical style, and supplemented by valuable
tables, treats the Saw scientifically, analyzing its action and
work, and describing, under the leading classes of Reciprocating
and Continuous Acting Saws, the various kinds of large
and small Hand Saws, Mulay, Jig, Drag, Circular, Cylin-
der and Band Saws, as now and formerly used for cross-
cutting, ripping, scroll-cutting, and all other sawing opera-
tions in wood, stone and metal, ice, ivory, etc., in this country
and abroad. With Appendices concerning the details of
manufacture, setting, sawing, gumming, filing, etc.; tables
of gauges and other valuable information. Elegantly printed
on extra heavy paper. Subscription price, \$1.50. Orders for
first edition received now.

Opera House, Denver, Col.

CITY LOTS

25x125 FEET

SITUATED IN NORTH DENVER,

FREE!

U. S. Mint, Denver, Col.

EVERY OTHER
LOT ABSOLUTE-
LY FREE!

Denver now has a population of 40,000. Great cities are the outgrowth of great countries.
Twenty years ago Denver was a small trading post on the frontier, now it is a large city, with
numerous Churches, Hotels, Theaters, Street-railroads, Gas-works, Water-works, Gold and
Silver Smelting and Refining Works, with a United States Mint, and is the great Railroad
Center of the West. There are seven First-class Railroads now running and connecting
with all the Principal and Branch Railroads from Maine to California. It is the Capital of
Colorado, naturally the richest State in the Union, and located in about the geographical
center of the United States. The climate is charming, with the best water and purest air
in the world, and the scenery is unequalled for beauty and grandeur. It is surrounded
by the richest Gold, Silver, Copper, Iron, Lead, and Coal Mines and Agricultural Lands in
America. It is now the headquarters for Colorado, Kansas, Nebraska, New Mexico, Wy-
oming, Nevada, Arizona, and Northern Texas. The rich mineral and agricultural resources
of this vast country will make Denver the largest and wealthiest city in the West.

WHY LOTS ARE GIVEN AWAY.

As the tide of immigration is now in this direction, it is the Company's interest to have
people locate in Denver and on their property. To encourage emigration here, the Company
will give to any one sending their name and address a warrant deed, in fee simple, for
one or more lots in North Denver, situated in Weld County, State of Colorado, in immediate
view of this beautiful city, the only charge being one dollar to pay the Notary Public fees
for acknowledging deed and conveyance. The Company does not give every lot away, but
each alternate one, and does not expect that every person who gets a lot in North Denver
will come here, but a great many will, and they will induce their friends to follow. The in-
creased population will soon make this property very valuable, and this Company retain
each alternate lot, which they hold at prices varying from \$25 to \$300, according to location.
For this reason the above proposition is made. The deeds are unconditional, not requiring
any one to settle or improve, but with full power to transfer and deed to others. The limit
to any one person taking advantage of this offer is five lots. This property is not hill-
side, mountain, or swamp, but is level, fertile, and has advantages for building
upon too numerous to mention. Full and satisfactory information, with indorsements
from our best citizens, will be furnished.

CERTIFICATE OF TITLE.

I, W. C. SANDERS, County Clerk and Recorder within and for said County and State, do hereby certify
to the above and foregoing to be true, and little complete to the land therein described according to the
records in my office. I further certify there are no abstracts or transcripts of judgments, taxes or other
leins standing against said land. In testimony whereof I have hereunto set my hand and added my official
seal this 2d day of August, A. D. 1879.

[SEAL] State of Colorado,) ss.
County of Weld,)

INSTRUCTIONS.

This Company will send by return mail, to any one sending within sixty days from the
date of this paper their names, P. O. address,
County and State, plainly written in full, a clear
warrant deed to lot 23 feet front by 125 feet
deep in North Denver, Colorado, clear of all taxes.
Applications for city lots must be accompanied
with one dollar for each lot to pay cost of making
and acknowledging deed, postage, etc. The lots
then can be sold and transferred at your pleasure.
Let all improve this opportunity to secure a home in
the richest State in the world. Deeds sent to any part
of the U. S. and Canadas. Address all letters to

ALLEN GOVERNOR.

This Governor is now being generally adopted through-
out the United States and Europe. It is without doubt
the

Most Perfect Engine Regulator in Use,

And will in most cases save its cost several times a year.
It is invaluable on a QUARTZ, FLOUR or SAW MILL
ENGINE, or in any Manufacturing Establishment, where
Regularity of Speed is desirable. By being able to run
the engine to its full capacity, these Governors have in
many cases added

Ten Per Cent. to the Produc- tive Capacity of a Mill,

Thus saving more than their cost every week in the
month. Every Engine to which this Governor is attached
will run with the throttle wide open. The speed of the
Engine can be changed by a simple adjustment of the
weights. It will give a UNIFORM SPEED WITHOUT
REFERENCE TO THE BOILER PRESSURE. It is simple
in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction.
Thirty days given for a trial, and if it does not fulfill all
that is promised, it can be returned at our expense.

In ordering, state the kind of engine, diameter of cylin-
der, stroke, speed, and average pressure.
Send for full descriptive circular.

PHOSPHATE SOAP

THE BEST soap for toilet use ever
manufactured. BEST because it con-
tains all the excellencies of the most
expensive foreign or American soaps
without their defects. BEST because
it combines strength with delicacy
in such a way that its strong deterative
qualities do not injure the skin.
BEST because it is the result of years
of study and experiment in the soap
manufacturing business, assisted by
modern chemical discoveries. BEST
because it contains ingredients bene-
ficial to the skin, which unite chemi-
cally with the soap in such a manner
as to increase its saponaceous quali-
ties. Every chemist familiar with
soap manufacture knows that some
ingredients which are in themselves
beneficial to the skin cannot be saponi-
fied; some are partially neutralized,
while others injure the quality of the
soap. There are soaps in the market
which are to some extent beneficial to
the skin, but they are inferior articles
for toilet use. PHOSPHATE SOAP
is the ONLY article offered to the
public which combines all the best
elements of toilet soap with medical
ingredients beneficial to the skin.

If your wife is in the habit of using
cosmetics of any kind, advise her to
give up the pernicious practice, as
the most harmless face powders ob-
struct the pores of the skin and
sooner or later injure the complexion,
while PHOSPHATE SOAP removes
all impurities and assists nature in
developing a natural, healthy and
beautiful skin.

It is an old proverb that an ounce of
preventive is better than a pound of
cure. Twenty-five cents invested in
a cake of PHOSPHATE SOAP will
save hundreds of dollars in doctors'
bills. It acts as a constant disinfect-
ant, preventing Salt Rheum and other
skin diseases.

If your wife will persist in the use of
cosmetics, buy her a cake of PHOS-
PHATE SOAP and tell her to use it
every night before retiring. In that
way much of the harm will be avoid-
ed, as the skin will thereby be able to
retain much of its natural vigor and
beauty.

No salve or ointment can heal a
wound or sore of any kind. Every
educated physician will tell you that
nature alone can do this. PHOS-
PHATE SOAP, by its cleansing,
soothing and purifying qualities, gives
nature a chance to act freely.

Natural beauty surpasses anything
which can be imparted by artificial
means. PHOSPHATE SOAP gives
health to the skin simply by removing
impurities and eradicating the poisons
which give rise to skin diseases.

Not only for daily use on the face
and hands, but for bathing the entire
body, there is nothing equal to PHOS-
PHATE SOAP. It is a thorough dis-
infectant and removes offensive odors
of every kind.

Ladies who have injured the skin by
the constant use of cosmetics may do
much to restore their faces to that
beauty which nature alone can give
by constantly using PHOSPHATE
SOAP.

For all diseases of the skin use
PHOSPHATE SOAP. There is nothing
like it for removing impurities
and giving the skin a healthy and
natural vigor.

Cheap toilet soaps manufactured
from rancid and refuse grease injure
the skin and are really more expen-
sive than PHOSPHATE SOAP, which
retails for 25 cents per cake.

Thousands of articles are palmed off
on the public which have no genuine
merit, but PHOSPHATE SOAP is the
result of modern discoveries of cele-
brated chemists.

PHOSPHATE SOAP costs no more
than other good toilet soaps, while its
medicinal qualities make it worth ten
times its price to every man, woman
and child.

If you want a nice article of Toilet
Soap and something that is beneficial
to the skin, buy PHOSPHATE SOAP.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Ad-
justed than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

CONTINUED FROM PAGE 325.

IDAHO.

YANKEE FORK.—*Herald*, Nov. 8: Judge W. F. Anderson handed us a rich piece of very fine smelting ore from the Uncle Ben mine, Bay Horse district. The vein was discovered near the surface, at which point it was only one inch wide, but at the depth of 30 ft opened out to a three-ft vein. The average across the ledge is \$92.75 per ton. A strike of very rich rock was made a few days since on the Charles Vainu ledge, summit of Mount Estes. J. O. Morrison, a short time since, found what promises to be a valuable quartz lode in his placer mine above the mouth of Jordan creek. This is satisfactory evidence that the quartz ledges on Norton hill extend across the Jordan to Bonanza bluff.

EBENEZER AND YELLOW JACKET MINES.—*Idaho City World*, Nov. 11: Hon. James H. Hawley, who returned from a trip to Canyon creek and Quartzburg, a few days ago, informs us that a large body of good ore has been struck in the Ebenezer mine, on Canyon creek. The ledge is from three to seven ft wide, but nothing is yet known of the extent of the ore body. Men have been put to work to develop it, and in a few weeks the company will know what they have. Men are kept at work on the Yellow Jacket, near Quartzburg, and good ore is being extracted.

MONTANA.

BALD BUTTE MINE.—The *Helena Independent* of recent date says: For several days past the workers have been driving a tunnel through what miners call a "fault," or ore which does not carry any considerable quantity of gold. A small vein of rich ore was always visible in the face of the tunnel, and, like the star in the east, steadily glimmered before the view of the miners and encouraged them to drive steadily ahead. And now it seems as if they will be well rewarded. Mr. Gilmore writes by mail, Messrs. Chumason, Chadwick and Tatum, that they have pierced through the "fault" and have three ft of quartz, through all of which gold can be seen. So easy is the quartz worked now that the miners pushed the tunnel 10 ft in two days' work. Yesterday the quartz was wined out on both sides of the tunnel, and one blast threw out over four tons of ore.

NEW MEXICO.

COONEY DISTRICT.—*Herald*, Nov. 8: N. J. Cooper arrived from Cooney district, Mogollon mountains, last Saturday night. He reports that mining is being pushed in that district, with the best of results. The Cooney mine, owned by Mr. Cooney and John A. Miller, of Fort Bayard, is the best developed in the district. It shows free-milling ore, the average assay, at the depth of 180 ft, being 230 ounces to the ton. Frank Vingo has a splendid body of ore on the Lady Godiva. It is between well-defined granite walls, and upon the surface measures two and one-half ft in width. Vingo & Cooper are driving a tunnel upon their Ocean Wave claim, and are now working in what they believe to be the sulphide of silver. Upon roasting, the ore shows bubbles of pure silver. There are some 15 mines in the district, and from 40 to 60 miners are at work. Wood and water are abundant in the vicinity of the mines, and the timber extends for many miles upon either side. New houses are going up, all built in a substantial manner.

OREGON.

ELLIOTT CREEK.—*Sentinel*, Nov. 12: Miners on this stream are reported doing well. Pickle, Smith & Co. last week struck very rich prospects. In running a cut they came upon an old channel where the gravel averaged 50 cents to the pan. Other miners on the creek are generally doing well. Eaton & Miller's claim is paying well.

JOSEPHINE CO. ITEMS.—Letter from Waldo to the *Sentinel* reports that mining operations are assuming a lively appearance. Preparations are being made for a long run. Prospecting has been the rage during this fine weather, and the mines that have lain dormant for years are being opened this winter. W. H. M. Co.'s hydraulic claim, containing 220 acres mining ground, conducted by Wimer & Simmons, will be ready for plying in about three weeks. This mine has been considered by old experienced miners to be one of the richest mines in southern Oregon. Two years have been consumed in constructing a cut, one-fourth of a mile in length, 60-ft bank. Large flumes have been placed in this cut for a tail race. They have a ditch four miles in length, carrying 1,500 inches, taking their water out of the East Fork of the Illinois river and dumping it into the West Fork. New flumes have been constructed wherever required throughout the entire distance. This winter they will have 140 ft pressure; 900 ft of iron pipe will be used with an 11-inch giant and 4-inch uzzle. Wessel & Co., Hydraulic mine, are making extensive preparations for a long run. The elevator used in carrying the dirt from their mine to the flume works to perfection. Rich prospects have been found beneath what was supposed to be a bedrock, but what proved to be a boulder formation, with good pay dirt.

WASHINGTON.

SKAGIT PLACER MINES.—Mitchell Thibert, an old and experienced miner, returned to Seattle a short time ago, from the newly-discovered Skagit gold mines. He states that his party was engaged six days in piling up Skagit river from Mount Vernon, the head of canoe navigation, and from thence was two and a half days making the trip overland to the diggings, packing from 75 to 100 pounds to the man, over a very difficult foot-trail, though not so bad as has been represented. At the time he left but little work was being done, claim holders generally waiting for the water to go down. On Butcher claim a wing-dam was being constructed for the purpose of draining the bed of the creek. The Boren claim has been worked down to the bedrock and found to be rich. Mr. Thibert prospected eight pans of top-gravel, from which he obtained 33 cents. This, he states, is much richer than any top-gravel found in Cassair. He also prospected five pans on the riurcock, from which he obtained 10 cents. Other parties are making \$5 per day panning top-gravel. Most of the claims will be very hard to open, the bedrock in many places being 12 to 20 ft below the surface. Claims are being located very fast. On claims already open work will be continued until December 1st, or later. As a general thing, however, operations will be suspended until spring. On the night of the 1st inst. ice formed to the thickness of three inches in the mines.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Hillside, Nov. 14th, \$3,500; Northern Belle, Nov. 10th, \$5,018.73; Bodie Con., Nov. 17th, \$30,000; Northern Belle, Nov. 12th, \$8,954.78; Hillside, Nov. 16th, \$3,500; Gila, Nov. 15th, \$3,061; California, Nov. 11th, \$13,569.55; Cou. Virginia, Nov. 11th, \$54,715.74; Northern Belle, Nov. 15th, \$7,327.60; Hillside, Nov. 20th, \$3,000.

In New York Government bonds are quoted at 103 for 4s of 1907; 102½ for 5s of 1881; 106½ for 4s; sterling, \$4.81@4.84; silver bars, 115½; silver coin, 9@9½ discount.

The future Queen of Spain, Archduchess Marie Christine, has officially renounced her right to the Austrian succession.

Decisions in Patent Cases, Etc.

U. S. Circuit Court, Northern District of Illinois.

Irwin et al. vs. McRoberts et al.

Decided July 8th, 1879. Motion for preliminary injunction. Blodgett, J.:

1. On an application for preliminary injunction, a re-issued patent containing claims not in the original patent, and alleged to be infringed by the defendant, is to be treated as a new patent, so far as their standing as to acquiescence and acceptance by the public is concerned.

2. That the device patented has never been put on the market as an operative article for sale, nor the patent passed the ordeal of litigation, nor its validity accepted by the public, are circumstances to be taken into consideration in determining the right of a party to a preliminary injunction.

Injunction refused, on condition that the defendant shall enter into a bond in the penal sum of \$10,000 for the payment of any damages that the complainants may recover.

Cooke et al. vs. the New York Central and Hudson River Railroad Company.

Northern District of New York. Decided July 6th, 1879. Blatchford, J.:

Re-issued letters patent No. 7,690, granted to C. L. Cooke May 22d, 1877, for an improvement in railway switches, for which original letters patent No. 121,158 were granted Nov. 21st, 1871, cover a patentable improvement.

There must be a decree for the plaintiffs for a perpetual injunction, and, under the stipulation of the parties, a decree for the plaintiffs for \$3,750, damages for past infringements and for costs.

Barker vs. Stowe. Same vs. Newhall.

U. S. Circuit Court, Northern District of New York.

Decided September 2d, 1879.

1. Under Equity Rule 88 an application for rehearing in a patent case cannot be entertained unless made within the term at which the final decree was entered and recorded, such cases being appealable to the Supreme Court.

2. An affidavit in support of a motion for a rehearing is not sufficient if it merely states that the party "made every effort to obtain the testimony (rebutting), but was not aware that he could do so," without stating what efforts were made, or that he visited any of the places mentioned or saw any of the persons named in the testimony sought to be rebutted.

3. If the plaintiff is surprised at the testimony of one of his witnesses, he may ask time to investigate in regard to it, on the ground that no notice of it had been set up in the answer.

The motions are denied.

Blake et al. vs. Boisselier et al.

Eastern District of Missouri. Decided March

term, 1879. Treat, J.:

A provisional injunction may not be obtained simpliciter without giving bond or security when a party has only some vague and indistinct right, and the order may result in injury to the business of the defendant, which is not necessary for the maintenance of the complainants demand, and may be ruinous to the defendants.

To preserve the status of the parties until a final hearing, without injury resulting, the order will be simply that the defendants keep an account of the articles manufactured by them and also of those by them sold.

The Odorous Excavating Apparatus Company vs. Clements.

District of Maryland. Bond, J.:

1. A decision in a previous suit in the same court between other parties determining the validity of the same reissue and the identity of the defendant's apparatus will not be disturbed without cogent reasons.

2. An apparatus for cleaning privy-vaults which draws the matter directly into the receiving vessel by a vacuum created therein by an air-pump, differs in principle from an apparatus which first draws the matter into a pump and then forces it out of the pump into a receiving vessel.

3. An apparatus for cleaning privy-vaults which draws the matter directly into a cask which is portable and conveniently handled, is not anticipated by earlier inventions, operating upon the same principle, where the receiving vessel is a large tank mounted on wheels, or in which the receiving vessel is permanently secured to a framework.

4. It involves invention to place a float-valve at the mouth of an air ejection pipe in a night-soil cask so as to close such pipe and stop the operation of the air-pump when the cask is filled, although similar valves were old and had been used in steam boilers and water tanks to close ejection passages.

5. The validity of reissue No. 6,962, dated February 29th, 1876, to Lewis R. Keizer, as assignee, reaffirmed.

The fact of infringement is admitted if the complainant's patent is sustained, and a decree will be passed in accordance with this opinion, and the cause referred to a master to ascertain the damages.

Ex-parte Hoffman.

Decided Aug. 26th, 1879. Motion for rehearing. Paine, Commissioner:

A motion for a rehearing cannot be entertained

after the case adjudicated has been amended by the removal of one or more of the claims. The only recourse of the applicant is to a new interlocutory appeal upon a refusal by the Examiner to consider the merits of the claims in their amended form.

Brushes—Ex-parte Dinkelbiller.

Decided August 26th, 1879. Interlocutory appeal from the Primary Examiner.

A claim for a rotary brush, with handles at right angles to each other connected by a frame, cannot be joined with a claim for a rotary brush with handles at the opposite ends of its axis, for the two sets of handles do not co-operate with each other, nor are they used either simultaneously or successively in the accomplishment of any result.

The decision of the Primary Examiner is affirmed.

Report of the United States Land Office.

The telegraph brings from Washington a digest of the annual report of the General Land Office. The following shows the disposal of public lands in California, during the last fiscal year:

Taken for homesteads, 223,014 acres; purchased for cash under pre-emption entries, 114,228 acres; timber culture entries perfected, 15,619 acres; taken under the Desert Land Law, 24,067 acres; cash receipts from all sources, \$276,505; incidental expenses, \$48,342. Only about 5,900 acres were patented to the State of California last year under Federal grants for all purposes, 5,273 acres being the total for indemnity school selections. The total number of desert land entries in the whole country was 530, embracing an aggregate of 165,936 acres, or only about half the totals of the preceding year.

The desert land entries in Nevada aggregated about 28,000 acres; in Montana, 39,000; in Arizona, 15,000 acres, and in Oregon, 6,000 acres.

The General Land Office report incorporates large portions of a report received from Surveyor-General Wagner. It shows that only about \$30,000 was allotted for the survey of California agricultural lands, \$10,000 for timber land, and \$4,000 for private land claims, and about \$32,000 was advanced by settlers and railroad companies for surveys. Total number of acres of public lands in California surveyed during the last fiscal year was 1,910,531 acres, leaving about 41,000,000 acres still unsurveyed. Surveyor-General Wagner says that nearly all the lands in California now unsurveyed should be sectionized, without restrictions as to their character, and recommends the removal of all restrictions. He says grazing and other lands are so intermingled that it is practically impossible to properly draw a line of demarcation; and consequently small tracts of valuable land must be left unsurveyed. The restrictions have not resulted economically to the Government, as the surveys frequently necessitated by this patch-work system cost more than the saving, besides giving rise to much litigation on account of changes in the topography. He says it is imperatively necessary to complete the survey of standard and meridian lines and township exteriors at the earliest possible date, in order to avoid in the future the serious errors resulting from the present piece-meal system of subdivision into sections. They may then proceed as settlements demand and Congress makes appropriations. Wagner makes a strong argument for liberal appropriations, and shows that the policy of Congress in making such limited provision for surveys in California has operated injuriously to the best interests of the State and also of the National Treasury. He calls attention to the fact that the occupants of unsurveyed lands are unable to acquire title, and although the State has passed laws for the protection of these actual settlers, it also protects speculators in holding large tracts, without cost or taxation, which would be impossible if the lands were surveyed and subject to entry. In that event these tracts would furnish homes for a large number of families by simply fencing, using and occupying them. He reinforces his plea for increased appropriations by showing that much land in California, formerly considered worthless, is now discovered to be very valuable. He instances the San Joaquin valley lands, and also quotes articles from the *San Francisco Bulletin*, showing that public attention is being directed toward a neglected belt of land between the foothills and snow lines of the Sierra Nevada mountains, where there are thousands of acres sufficiently level for farming purposes. He also gives statistics showing the rapid development of California wine-producing interests. He remarks that even the scant products of the Mohave desert are now being utilized by the manufacture of paper from a species of cactus; but as this is too widely scattered to justify the purchase of land from the Government, and as the industry, although giving promise to become valuable to California manufacturing interests under favorable conditions, requires an outlay of considerable capital for machinery, he recommends that Congress be required to authorize these lands to be leased to any party desiring them for a term of years, the lands, however, to remain subject to entry under the homestead or pre-emption laws.

Gen. Wagner also argues that all money which may be appropriated by Congress for surveys in California would in a few months be returned to the Treasury by sale of land. Thus, for instance, the total amount expended last year in the survey, sale and disposition of public land

in California was \$103,747, and during the same period the sales yielded to the Treasury \$456,773. He also shows the necessity for liberal appropriations to bring up the long accumulated arrears of office work, and asks \$20,000 for that purpose, besides \$135,000 for ordinary land surveys, \$50,000 for timber lands, and \$10,000 for the survey of private land claims. Gen. Wagner recommends that the law authorizing homestead and pre-emption surveys to be made upon deposits of estimated cost, be extended to agricultural lands in mineral districts, and also to desert lands and timber lands. He says very little of the timber land in California has been surveyed, and as enormous quantities of timber are used in the neighborhood of mines, and as there are no adequate means of protecting unsurveyed lands, they are rapidly being despoiled. He therefore requests that the timber lands should be surveyed so that persons entitled to enter them under the law of 1878 may obtain title. He adds: "There is no danger that non-resident speculators would monopolize the timber lands under this law, for, aside from its safeguards, they would be no better able to protect the lands from speculation than the Government."

The Surveyor-General says in regard to mineral lands, that the rectangular system is so readily understood by all classes that it cannot be supplemented by any so-called scientific system; that the contract system of survey is better than the proposed system of salaried deputies; that the classification now made by Deputy Surveyors is as accurate as can be made at moderate cost, and that the whole matter should be left undisturbed. The total number of mines surveyed thus far in California is nearly 2,000.

News in Brief.

ALEKO PASHA has arrived at Constantinople. GREAT preparations are making in Spain for the King's marriage.

THIRTEEN persons were drowned Sunday at Islay, Scotland.

THE Vatican is to issue a new daily newspaper—the *Aurora*.

ABDUL-KADIR, the famous Algerian chief, is dead, aged 72 years.

GENERAL CALDINI, Italian Minister to France, has resigned.

BULLION in the Bank of England decreased £886,000 the past week.

W. F. WILCOX, an old citizen, died at Portland, Or., Sunday evening.

THE Sultan has ordered the re-equipment of the forts on the Dardanelles.

HEAVY gales on the English coast have caused much damage to shipping.

THE wife of Baron Manteuffel, Governor of Alsace-Lorraine, is dead.

PRESIDENT HAYES formally opened the Grand Fair at New York Nov. 17th.

A WOMAN and her two daughters were drowned Saturday near Columbus, Ind.

ONE of the Kahns and his brother are inciting an insurrection in Kohistan.

MEMORIAL services in honor of the late General Hooker took place at Boston.

THE shore end of the new French cable has been landed at North Eastham, Mass.

THE Czarowitch and Czarina and King and Queen of Denmark have arrived in Vienna.

THE war in New York against dealers in lottery tickets is being vigorously prosecuted.

A DROUGHT of alarming proportions prevails in the section of country around Petersburg, Va.

S. M. OAKES was shot and killed at Reno, Nev., Sunday night by Mrs. Dr. T. N. Snow.

THE inquiry into the Amera connection with the Cabul massacre has been commenced.

AN explosion of fire damp in a colliery near Wolverhampton, Eng., caused the death of six men.

It is reported from Paris that two French explorers have discovered the source of the river Nile.

SILVER in London is quoted at 53½d; consols, 97 15-16; 5% U. S. bonds, 103½; 4s, 106½; 4½s, 108½.

A SHIPMENT of flour was made from New York Saturday, destined for Queen Victoria's kitchen.

FORTY-NINE Afghans have been hanged for complicity in the massacre of the British Embassy.

THE German authorities have prohibited Russian steamboat traffic in the Prussian section of the river Niemen.

ENGLISH farmers and merchants, to the number of 120, some with families, left Liverpool lately for Texas.

REV. J. B. McNAMARA was installed at New York Sunday as Bishop of the Independent Catholic Church.

In a railroad accident near Alton, Ill., Saturday, a brakeman was killed and an engineer and fireman injured.

At Liverpool wheat is quoted at 10s 8d to 11s 6d for average California white, and 11s 5d to 11s 10d for club.

THE withdrawal of the greater part of the Turkish troops on the Greek frontier has been ordered by the Porte.

AUGUST WORHLER, who attempted to assassinate Dr. E. B. Foote in New York recently, committed suicide.

REV. ALEX. MACDONOCHIE has been suspended from his ecclesiastical functions in England for ritualistic practices.

A SCHOONER foundered Friday near Point au Pelee, Lake Michigan, and the entire crew, with one exception, perished.

PATENTS AND INVENTIONS.

List of U. S. Patents and Trademarks for Pacific Coast Inventors.

(From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and S. & Foreign Patent Agents.)

FOR THE WEEK ENDING NOVEMBER 4TH, 1879.

- 221,285.—TAP FOR TIN-CANO, ETC.—J. T. Cooper and J. Wagner, Silver Reef, Utah.
- 221,230.—VALVE MECHANISM—Geo. E. Dow, S. F.
- 221,224.—STEAM ENGINE—A. Ehrst, S. F.
- 221,221.—FARTHING WHIP LAMIES—J. J. Fowler, Ukiah.
- 221,205.—WRENCH—W. A. Heath, Hallsburg, Cal.
- 221,325.—CAN FOR HERMETICALLY SEALED GOODS—C. C. Lane, New Westminster, B. C.
- 221,175.—EAR-RING—W. A. L. Miller, S. F.
- 221,316.—ATTACHMENT FOR INVALID BEDS—R. O'Donnell, San Francisco.
- 221,184.—MECHANICAL CALCULATOR—S. Petty, Volcano, California.
- 7,766.—CHECKER—Trademark—F. Korbel & Bros., S. F.
- FOR THE WEEK ENDING NOVEMBER 11TH, 1879.
- 221,463.—CAN—C. C. Lane, New Westminster, B. C.
- 221,890.—PISTON FOR HYDRAULIC CYLINDERS—F. A. Bishop, S. F.
- 221,527.—SPRINKLER FOR RAILWAY RAILS—M. F. Craig, Nevada City, Cal.
- 221,454.—WEATHER STRIP—James C. Gibson, S. F.
- 221,457.—REVERSIBLE PLOW—O. Haskin, Cambria, Cal.
- 221,008.—SPARE—J. E. Parnett, Fort Pomona, Dak.
- 221,470.—SAW MACHINE—S. Petty, Volcano, Cal.
- 221,473.—GUIDE FOR STRENGTH OF STAMP-MILLS—W. Raup, Park City, Utah.
- 221,021.—GRAIN SEPARATOR—W. H. Silsby, Chico, Cal.
- 221,432.—DRILLING MACHINE—Geo. Uhl, Sacramento, Cal.
- 221,483.—WASTE-PIPE CLEANER—E. J. Verrie, S. F.
- 221,485.—ELECTRO-THERAPEUTICAL BELT—C. N. West, San Juan South, Cal.
- 2,116.—FISH.—"MEJOR CAFE MOLINO DE COSTA RICA PRIMERA CALIDAD"—Label—E. Guittard, S. F.

The following foreign patents have been issued to residents of this Coast:

English Patents

- Which have passed the great seal:
- 757.—IMPROVEMENTS IN MOTORS—E. J. Molera and J. C. Cebrian, S. F. Feb. 25, 1879.
- 1,057.—PUMPING MACHINERY—E. J. Molera and J. C. Cebrian, S. F. Mar. 18, 1879.
- 1,102.—CANDLE-STICK—A. J. Smith and E. W. King, Ukiah, Cal. Mar. 19, 1879.
- 2,250.—SAW MACHINE FOR SINKING CARPETS, ETC.—J. Hease, S. F. June 6, 1879.
- 2,727.—MACHINERY FOR GRINDING OR TURNING HARDENED METAL SURFACES—J. H. Gowan and C. Daniel, Carson, Nev., July 4, 1879.
- 2,889.—WRENCH—A. Jackson and J. J. Dunn, S. F. July 22, 1879.
- 2,965.—BENCH-LOADING FIRE-ARMS—A. Swingle, S. F. July 22, 1879.
- 3,255.—HOOKS—F. Kortick, S. F. Aug. 13, 1879.

Canadian

- 10,307.—SYSTEM OF LIFTING—E. J. Molera and J. C. Cebrian, S. F. July 29, 1879.
- 10,363.—VAPOUR ENGINE—W. P. and W. T. Wood, Westinghouse, Cal. Aug. 14, 1879.

Victoria

- 2,080.—MACHINE FOR PULVERIZING ORE AND AMALGAMATING METALS—A. B. Paul and J. T. Davis, S. F. June 21, 1879.

German

- 7,904.—ROCK DRILLING ENGINE—W. W. Dunn, S. F. Sept. 4, 1879.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

CAN FOR HERMETICALLY SEALED GOODS.—

Chas. C. Lane, New Westminster, British Columbia. The ordinary form of cans in which salmon and other fish are hermetically sealed, necessitates the cutting of the fish into pieces of small size, and its appearance when prepared for the table is not satisfactory. To obviate this, large, fish-shaped cans have been made by stamping out two pieces of tin, each forming the entire length of the fish. Besides necessitating the use of a large and expensive size of tin, which will cut to waste a great deal, these cans can never be finished until the fish has been placed in them, and a longitudinal seam of double the length of the fish must be soldered by hand, as the mechanical bath cannot be depended upon to make a tight joint without blowholes after such a can has been filled. Besides this, each can must fit its fish closely enough to prevent movement to preserve the fish, and no adjustment being possible, the time taken to select cans to fit fish render this method too slow, costly and impracticable. This invention consists in the formation of a can in two parts, the parts, respectively, being approximately of the shape of the head and tail half of a fish divided transversely to its length, and this two-part can is so fitted that it may be adjusted longitudinally to fit the length of the fish. By this construction, a fish-shaped can may be formed from sheets of metal of ordinary size without undue waste, and by reason of the adjustability of the parts, the halves can be manufactured in quantity and by the aid of the mechanical bath, so as to have the requisite number of cans on hand when the canning season commences, and from the peculiar construction of the can, the amount of soldering to be done when the fish is placed in the can is reduced to a minimum.

TUYERES.—Thomas McCaffery, S. F. Patent 220,766, dated October 21st, 1879. With this invention either one of the various styles of blast openings may be used according to the work on hand. The improvement consists in providing a flat metal plate having perforations

of different sizes and shapes, said plate having rack-bars on its lower edge, so that a rack-wheel operated by a crank may move said plate back and forth in a case provided for it enabling the workmen to bring either one of the perforations under the hole in an upper plate through which the air passes from the bellows to the fire.

WINDMILL.—Z. and F. M. Cottle, Oakdale, Stanislaus county, Cal. Patent 2,0,751, dated Oct. 21st, 1879. This wheel is intended for pumping water in such localities as have prevailing winds from one direction for a length of time. In the great valleys of California the prevailing winds of the summer months are westerly and the windmill is set up so as to face the westward. Occasionally, however, the wind will blow from an opposite direction for a short time and the motion of the wheel would then be reversed. In order, however, not to have the shaft also reverse, a supplemental pin is placed between the spur-wheel and a large pinion so as to change the motion.

WEATHER STRIP.—James C. Gibson, S. F. Patented Nov. 11th, 1879. No. 221,454. This invention consists in the employment of a peculiar elastic strip, secured to a movable plate in a recess at the bottom of the door, so that when the door is closed the strip is forced down tightly against the sill, so as to prevent the entrance of wind and rain and make a close joint. On the opening of the door the strip is thrown back into the recess or against the bottom of the door by its own elasticity. The peculiar construction of the weather-strip is such that no supplemental hinges are necessary, the substance of which it is composed being elastic, and while it forms a tight joint when the door is closed, it is thrown up out of the way as it opens.

REVERSIBLE PLOW.—Ozro Haskin, Cambria, Cal. Patented Nov. 11th, 1879. No. 221,457. This invention relates to certain improvements in reversible plows in which the land-side and mold-board are alternately changed with reference to the beam, so as to turn the furrow in the same direction, as the plow is drawn back and forth across the field, being especially applicable to hillside plowing. It consists in a right and left mold-board attached to the double reversible land-side hinged to the vertical swiveling axis of the plow beam, and also in a method of holding and locking the plow in position.

HYDRAULIC WASTE PIPE CLEANER.—E. J. Verrie, S. F. Patented Nov. 11th, 1879. No. 221,483. This invention relates to a novel hydraulic waste pipe cleaner, and it consists in the employment of the pressure which is present in the water mains and pipes, and in a means for making a direct communication between the service-cocks and the waste pipe, whereby the pressure of the water pipe is transmitted to the waste pipe, and this pressure is enhanced to any desired extent.

PUT YOUR TRADE-MARKS OVER YOUR GOODS, YOU who have them; and you who have them not design and procure one as soon as possible. A good trade-mark, once recognized and well known, is a fortune in itself. People get accustomed to buying goods of that special brand, and will take no other. Display your trade-marks with your wares. It's like meeting a friend to see a familiar trade-mark. Dewey & Co.'s Scientific Press Agency, San Francisco, is the place to apply for United States patent trade-marks and other patents, caveats, etc.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send one but worthy man.

- J. L. THARP—San Francisco.
- B. W. CROWLEY—California.
- A. C. KNOX—Pacific Coast.
- S. V. BLAKELEE—California.
- G. W. MCOREW—Santa Clara county.
- J. B. BACHELOR—Shasta county, Cal.
- JAMES ROGERS—Oregon and Washington Ter.
- THOS. H. MARINE—Nevada, Idaho and Montana Ter.
- CATT. W. H. SSANES—Arizona.
- M. P. OWEN—Santa Cruz County.
- H. E. HALLETT—Los Angeles County.

INVENTORS, and others interested, will receive DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

How TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Alpha Hydraulic Gravel Mining Company.

Location of principal place of business, San Francisco, California. Location of works, Washington Township, Nevada County, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the Second day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
Alexander Girvin.....	8	1000	300 00
Mrs. Catharine Girvin.....	9	1000	200 00
Thomas Redman, Trustee 3		500	100 00

And in accordance with law and an order of the Board of Directors, made on the second day of October, 1879, so many shares of each parcel of said stock as may be necessary will be sold at public auction at the office of the company, 216 Sansome street, San Francisco, Cal., on the Thirtieth day of December, 1879, at the hour of one o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale. JAMES IRELAND, Secretary.

Office, No. 210 Sansome street, San Francisco, Cal.

Butte Hydraulic Mining Company.—Prin-

cipal place of business, San Francisco, California. Location of works, Butte county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 31st day of October, 1879, an assess-

ment of Ten Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at room 3, No. 220 Sansome street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 2nd day of December, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Twenty-second day of December, 1879, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

L. L. DENNEY, Secretary.

Office, Room 3, No. 220 Sansome st., S. F., Cal.

Catacart and Wide West Hydraulic Gravel

Mining Company. Principal place of business, San Francisco, California. Location of works, Elko Mining District, Calaveras County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of November, 1879, an assessment of Twenty five cents (25 cts) per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at 263 Kearny street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on Monday, the 22nd day of December, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 17th day of January, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

WM. B. LAKE, Secretary.

Office, 263 Kearny Street, San Francisco, Cal.

Land Purchasers' Association.—Location

of principal place of business, San Francisco, California. Notice is hereby given that at a meeting of the Board of Directors, held on the 5th day of November, 1879, an assessment of six dollars (\$6) per share (being the balance of the 43d installment on the subscription to the stock), was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at No. 641 Sacramento street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 4th day of December, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 31st day of January, 1880, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

C. S. WRIGHT, Secretary.

No. 641 Sacramento street, San Francisco, Cal.

Numa Mining Company.—Principal Place

of business, San Francisco, California. Location of works, Humboldt County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 23rd day of October, 1879, an assessment (No. 2) of Two Cents (2 cts) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 328 Montgomery St., room 21, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 24th day of November, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 18th day of December, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

DAVID WILDER, Secretary.

Office, 328 Montgomery St., Room 21, San Francisco, Cal.

POSTPONEMENT.—The day of delinquency of the above assessment is postponed to December 22nd, 1879, and the day of sale to January 12th, 1880. By order of the Board of Trustees.

DAVID WILDER, Secretary.

Room 21, 823 Montgomery street, San Francisco.

Annual Meeting.—Office of the Godfrey

Oravel Mining Company.

NOTICE.—The annual meeting of the above named company will be held at the office of the company, 302 California street, rooms 3 and 4, second floor, on Monday, the 1st day of December, 1879, at 2 o'clock P. M. of said day, for the election of a Board of Directors, and such other business as may come before said meeting. Transfer books will be closed on Saturday, 22nd day of November, 1879, at 12 o'clock M.

J. M. BUFFINGTON, Secretary.

D. H. TWING, President.

ANNUAL MEETING.

Napa Con. Quicksilver Mining Company.

The regular annual meeting of the Napa Consolidated Quicksilver Mining Company will be held at the office of the Company, room 7, Safe Deposit Building, 323 Montgomery street, San Francisco, California, on Wednesday, the twelfth day of November, 1879, at the hour of 2 P. M., for the purpose of electing a Board of Directors to serve during the ensuing year, and the transaction of such other business as may come before the meeting. Transfer books will close on Saturday, November 8th, 1879.

WM. W. PARRISH, Secretary.

Office, room 7, Safe Deposit Building, 323 Montgomery street, San Francisco, California.

POSTPONEMENT.—The annual meeting of the above named Mining Company is hereby postponed until Wednesday, the 26th day of November, 1879, at the same hour and place.

W. W. PARRISH, Secretary.

Stock Dividend Notice.

OFFICE OF THE

Gila Silver Mining Company,

Room 7, Safe Deposit Building, No. 328 Montgomery St., San Francisco, Cal., October 21, 1879.

At a special meeting of the stockholders of the above named Company, held this day, a Stock Dividend of 20 per cent. was declared, payable immediately, out of the capital stock owned by the Company.

All stockholders are requested to send their stock to the office of the Company before NOVEMBER 24th, 1879, and receive the dividend due thereon.

WM. W. PARRISH, Secretary.

POSTPONEMENT.

Diana Mining Company.

The day of delinquency of the above assessment is postponed to November 17th, 1879, and the day of sale to Friday, the 15th day of December, 1879. By order of the Board of Trustees.

J. T. MCGEOGHEHAN, Secretary.

Office, 318 Pine St., rooms 13 and 14, San Francisco.

Traveling Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Captains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.
32 Fremont Street, San Francisco.

Books for Miners and Millmen

KUTTEL'S ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated. 142 pages. 1870. A valuable and carefully written work. Postpaid, \$2.50. Published and sold by Dewey & Co., S. F.

KUTTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 672 pages and 83 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Postpaid, \$10.50. Sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated. 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Postpaid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Terms, etc., 1877. Pocket size, and very handy and convenient for miners. Postpaid, \$1.00. Sold by Dewey & Co., S. F.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

Secure Patents and TRADEMARKS.

Through Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from scouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

PATENT LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Miners, Guano Works, White Lead Corroding, Fading Threshing Machinery and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

SETH MARSHALL, Jr., Agent,
309 California Street, San Francisco, Cal.

Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no hack or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Amusements.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, hy which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance hy local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally hy a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in case of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS
OFFICE, No 202 Sansome St., San Francisco.

Superiority of Prehistoric American Wares.

It is assumed as a fact by Mr. Conant in his new work entitled "Footprints of Vanished Races," that the Indian tribes found in this country by the earliest European voyagers, were not the race which originally inhabited the continent, nor even the descendants thereof, and that the race of people which preceded them were not the ancestors of the Indians, in fact, had nothing in common with them, and no traditions ever descended to them.

There are many evidences which are cited to support this view of the matter, and one in particular, which demonstrates that the prehistoric American was a superior being to the prehistoric European. From the articles fashioned by their hands, their pottery and other wares, there is no doubt of the superiority of American prehistoric wares over those of Europe. The number of vessels of pottery which have been taken from the mounds in Missouri, is prodigious, and almost endless in variety. In one instance nearly one thousand pieces of various sizes and great diversity of form and workmanship were obtained from a single burial mound. Although the skill displayed in everything these remote people manufactured from clay is superior to their contemporaries in the so-called old world, there are many striking resemblances common to both. In the ceramic arts particularly, great ingenuity is displayed, and the fortunate fact that earthenware is of an almost imperishable nature, has enabled us to obtain and preserve the records of these ancient races and draw quite correct conclusions from the analogies presented in their successful attempts to imitate to the forms of beasts and birds which were seen every day. Particularly is this contemplation, observation and affectionate communion with nature observable in the potteries of the ancient Americans. Dr. Foster, in his "Prehistoric Races of the United States," says that in the plastic arts the mound-builders attained a perfection far in advance of any samples which had been found characteristic of the Stone, and even the Bronze Age of Europe. Sir John Lubbock remarks that "few of the British sepulchral urns, belonging to the ante-Roman times, have upon them any curved line. Representations of animals and plants are almost entirely wanting." They are even absent from all the articles belonging to the Bronze Age in Switzerland and in Western Europe generally, while ornaments of curved and spiral lines were eminently characteristic of the American Mound-builders. The ornamental ideas of the Stone Age were confined, so far as we are able to ascertain, to compositions of straight lines, and the idea of a curve scarcely seems to have occurred to them. The most elegant ornaments on their vases were impressions made by the finger nail, or by a cord wound round the soft clay. "The commonest forms of the Mound-builders' pottery represent kettles, cups, water-jugs, pipes, vases, etc.," continues Dr. Foster. Not content with plain surfaces, they frequently ornamented their surfaces with curved lines and fretwork. They even went further, and molded images of birds, quadrupeds, and of the human form. The clay, except for their ordinary kettles, where coarse gravel is often intermixed, is finely tempered, so that it did not warp or crack in baking. The utensils, when completed, had a yellowish or grayish tint.

Some of the small jugs or hottles have nicely adjusted stoppers, and the hottles themselves made of much finer materials than ordinary wares, and quite thin, but so well baked that they seem as tough and strong as our own ware. The outlines of the human faces and heads of birds, although somewhat crudely expressed,

exhibit much to admire, especially in the forms of the birds themselves. The flow of their outlines evinces a degree of refinement of feeling which could only result from a culture of the sense of beauty, requiring a long time for its realization. In the case of heads, the openings of the jugs, or the mouths, were all made on the back side of the head—a uniform practice. In the representations of the human figure such fidelity to nature is observable that it is difficult to believe that they are not portraits. Different varieties of ducks were molded in which the shape of the head, line of neck, etc., together with the nicest distinctions, in particular varieties, are expressed with remarkable skill.

The evidences of man and animals in the remote ages of prehistoric time seem to demonstrate that evolution had not then commenced, but that the types which existed then are the same as the objects that exist now. The whole subject is one of intense interest, inasmuch as future discoveries may establish the theory that the cradle of the human race existed in America. Many of the bayous on the Mississippi river have been demonstrated to be artificial canals dug by these ancient people, who exhibited thereby an engineering skill in

COPE & MAXWELL MFG CO'S COMBINED STEAM PUMP AND ENGINE.

addition to their artistic accomplishments, which moderns are not slow to copy.

TRINITY COUNTY QUICKSILVER MINES.—Some time ago we published a list of five counties in California which contained quicksilver mines. Trinity county was not mentioned for the reason that we had no data concerning the product of that county. The *Weekly Trinity Journal* has obtained information about the Altoona mine, in that county, and says: "Mr. Ch. Allenberg, Secretary of the Altoona quicksilver mining company, has kindly answered our inquiry with the information that the product of the Altoona mine for the last three years amounted to 5,674 flasks of quicksilver. This is 957 flasks more than was produced by the Oakland mine, in Sonoma county, for the same period." The quicksilver industries of this State are very important. The development of our gold mines will give quicksilver an impetus which will finally establish its production upon a safe paying basis, which market fluctuations elsewhere cannot affect to any great extent.

ONE of the mines of the Pennsylvania coal company at Pittsburg, Pa., has caved in. The damage will be considerable, and will throw a large number of men out of employment for some time.

Combined Steam Pump and Engine.

We illustrate herewith the Cope & Maxwell Manufacturing Co's. patent double acting crank and fly wheel steam pump, which is admirably adapted for furnishing motive power for other work at the same time.

The pump piston rod can easily be disconnected by the removal of a key from the cross-head of the engine, forming a simple, compact and powerful steam engine, having all the advantages of the best stationary engine.

The framing, slides, steam cylinder, steam chest and crank, shaft bearings, are cast in one piece and the arrangement of the entire machine is so simple and convenient that full access is had to any one part without disturbing any other. This machine is provided with a good cross-head and ample bearing on slides; the pitman connections are very long so they have no tendency to force the piston and pump rod sideways in the stuffing boxes, thus avoiding the great trouble and annoyance incident to those pumps having short pitmans, Scotch yokes and no slides. The facility with which

Salmon River Improvements.

It appears that the region of country about the sources of the south fork of the main Salmon, Wood river and the southern branch of the Boise river in Idaho, have been thoroughly prospected during the past summer, the work resulting in the discovery of a great number of valuable gold and silver-bearing ledges. Enough has been accomplished to establish the permanence and value of these ledges, and to open up a new and rich field for future mining operations. The mineral belt in which these discoveries are located, extends from the old emigrant road on Wood river to the valley of the South Salmon a distance of about fifty miles.

The country, however, is not settled, and means of communication are wanting, particularly good roads, without which developments must be delayed indefinitely. To meet this want several parties of Rocky Bar have formed an association and given notice that they will make application to the Board of County Commissioners of Alturas county at their January session, for a franchise or privilege to construct a wagon road from the Lower Wood river, through this belt of new mines to Bonanza City.

The mining districts which will be traversed or very nearly approached by this road, are Mineral Hill district, ten miles above the point of starting on Wood river, where a large number of rich ledges have been discovered. This district is situated on the west side of Wood river. Next follow the Jim Wincher, Warm Springs, Little Smokey and Black Bar districts, when we come to Wood River district, where Galena City has been located and laid out. Thence crossing the divide at the head of Wood river to the waters of South Salmon, Smiley, Sawtooth and Laks districts are passed. In most of the ledges in all these districts very rich ore has been found, and some of the ledges have already been bonded for large sums.

It is confidently expected that the coming year will witness the completion of the extension of a branch of the Utah Northern railroad to Wood river, for the purpose of securing the Idaho trade.

The starting point of the proposed wagon road is on the survey already made for the line of the railroad. The entire length of the wagon road from Lower Wood river to Bonanza City, will be about 103 miles, which will be from 60 to 75 miles nearer to the line of the railroad than by the way of Challis.

PULVERIZER AND AMALGAMATOR.—Edward Y. Harrison, of Victoria, has perfected some improvements in "Berdan hasins," comprising machinery for both pulverizing and amalgamating. The improvements have reference to that class of pulverizing and amalgamating appliances in which a mechanical pulverizer rolls around the inside of a rotating hasin set at an angle, like what is commonly known as the Berdan hasin. The side and bottom of the Berdan hasin form one continuous curve, so as to accommodate themselves to a ball or spherical pulverizer. Mr. Harrison, however, makes his hasins with flat bottoms and sides, placed at such an angle to each other as to accommodate themselves to a conical pulverizer resting and revolving on the side or wall. He also introduces a ledge, projecting inward from the upper part of the side or wall, in which ledge are openings for the passage of the material treated. The latter improvements may be applied to an ordinary Berdan hasin, if that shape of bottom is preferred.

THE merchandise exports of the past week at San Francisco were valued at \$676,464, a decrease of \$154,006 on those of the previous week.

A PRIVATE letter from a well-informed person at St. Petersburg states that intelligence has been received in official circles at St. Petersburg to the effect that the British government intends to occupy Herat next spring, in alliance with Persia. The writer adds that the news is generally credited.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

The Debris Question or Cleaning the Rivers for the Gold.

EDITORS PRESS:—This question, which at first attracted but little attention among miners, has since the action taken by the city of Marysville, and the decision made by Judge Keyser on the subject, become one of considerable importance, and must receive a consideration not before given it.

At first blush one will say, it is right to stop this eternal drifting of the mountains to the seas—the raising of river beds, by which towns and lands are inundated every season, and, that unless a stop is put to it, we may expect in time to see the mountains leveled to their base, and the bay of San Francisco transformed into an arid desert.

While there is cause for attention to the matter, the whole proceedings against the hydraulic miners has a very farcical cast, and certainly unworthy the spirit of the age, and of California spirit especially, when we consider the fact that mining built the city.

It would have been much more to the credit of the corporation of Marysville, to have offered a reward of \$1,000 or \$5,000, if you please, for the best plan for overcoming the difficulty, rather than commence suit against the gravel miners of the Yuba, and thus seek to destroy so important an industry as hydraulic mining. That gravel mining is to be abandoned in this State, because the debris washes towards the sea, through sloughs, ravines and rivers tending hitherward, is simply an absurdity. When it comes to overflows, Marysville and all the surrounding country, was deluged before ever hydraulic mining began, and oftener before than since.

We will admit the fact that the debris during the drier part of the seasons fills the river, but it is unreasonable to suppose that if a smaller body of water will bring down the debris and fill the river then, that the larger body of water occasioned by the winter rains, and which sometimes raises the streams 30 to 40 feet in a day, will not carry the debris previously deposited on and out, and with the swiftness with which the waters come down, so that we may say the overflow is not so much on account of debris previously deposited as the unexpected rush of immense bodies of water and debris.

There are many questions to be considered in connection with this debris subject, and at the end of it, we certainly will be wiser than we are to-day; and I doubt not but the State and people will be benefited by the agitation, and the injury to the gravel interest be but temporary. As before observed, it would have been more prudent for Marysville to have pursued a different course at all events, as she has let the worst go on for 25 years without complaint, and could have stood it a year or two more, in endeavoring to solve the problem, to no ones disadvantage, and for the good of all concerned. We know, that in every mining obstacle, the times have brought forth a something whereby all disadvantages were overcome. When we look to the days of the rocker, and up to the period when it ceased to pay, we find there comes in the sluice bar and "tom," by which man's labor was rewarded. This, in course of time becoming unprofitable with hand labor, genius brought forth the pipe and "giant," and still labor moved on with proper compensation. And so it is in every requirement. Some way or other we override the difficulties. And so should this question be considered: not how to destroy hydraulic mining, but as to the best plan for obviating any disadvantages that arise from it. It strikes my mind that the times have brought forth, as far as the river is concerned, the very machinery to accomplish the work, and in fact, the debris can be turned to such a benefit, that the more the miner will shovel the sand towards the rivers the better the lower counties will like it. There has recently been invented and brought into practical use a centrifugal pump, having a capacity for raising, say 6,000 cubic yards of earth every 24 hours, and elevating the same 20 feet above the water line. By a mechanical device, this pump has a sweep of 40 feet, so we may say it can clear the river bed 40 feet and deposit the debris on the low lands, elevating and enriching much of it at the same time. Then here comes in another question. To clean the Yuba, American, San Joaquin and Sacramento rivers in this way, what may be the gold product by washing this material after raising it, and in the operation of depositing "on shore?" Who knows, there may be "big money" in the operation of handling 6,000 cubic yards of these river sands every 24 hours, and in thus washing it for gold, to say nothing of the extra wheat crops which the new land would yield, or the improved value of the landed property. As to the gold question, many years ago, I had the "muddy water" of the Sacramento river, opposite Sacramento city, tested, and enough gold was obtained, which, when calculated by thousands of gallons of the water flowing daily, made millions of gold which yearly flowed on to the ocean. (I published a statement at the time.) If so much gold passes

on in "muddy water," how much coarser gold must be deposited in these rivers which receive the debris from the mountains. With machinery such as I speak of, enlarged if you please, sweeping these rivers, moving, say, 10,000 tons a day, how long would it take to settle this debris question? We will set this gold question on one side, and simply take up the clearing the rivers and securing the main land from overflow. One of the most sensible propositions on the subject, to my mind, was published in the *Chronicle* of this city some 10 days ago, entitled "Rivers, and River Diking." I will extract as follows:

"The natural channels of our rivers from the points where they enter the level plains and agricultural lands are not large enough to carry the waters drained into them in a very rainy season. They never were large enough. The floods of 1849 and 1852, which occurred years before the era of hydraulic mining, and when the low-water level at the State capital was 16 feet lower than it is now, deluged that city and all the plain region as much as the floods of 1862 and 1867. An equal rainfall this year or next would probably overflow even the high dikes erected along the Sacramento for the protection of that region, unless the dikes on the Yolo side should give way and afford an outlet above the city for the escape of the surplus water."

"If, then, we should assist nature by widening the channels of our rivers from the points where they enter the plains, and are liable at every season of extraordinary flood to deluge the country and destroy the land and crops by discharges of debris, we would not only be secure from these periodical floods, but turn a positive evil into a great benefit."

"In other words, instead of building the dike close up to the water, as has been the uniform practice, it should be constructed a hundred or two hundred feet back from the natural channel."

"The natural bed of the Sacramento at the railway bridge is about 800 feet. If the dikes on both sides had been constructed, say 400 feet back from the natural banks of the stream, the new channel would be large enough to carry all the waters discharged into the river by our highest floods. Its capacity would be just double what it is. A dike five feet high would secure the country against overflow as well as one of ten feet in a channel of only half the width. The loss by the adoption of this plan would be nothing more than the narrow strip of land surrendered to the river channel. The gain would be the difference of the labor and expense of constructing and maintaining a dike five feet high and one of ten feet. It would in the course of a few years pay back ten times over the value of the surrendered land, and every land-owner would be supplied with the means of unlimited irrigation at the lowest possible expense. For the season when irrigation for our staple crops is most needed is the season of high water, when the rivers are above their natural banks."

Now suppose this proposition was entered upon, how insignificant would be the loss by expense, when compared with the question of the profit to the State of an industry like hydraulic mining. Now I will throw in a suggestion in connection with the above, or rather make a combination. 1st. Widen the streams by diking them back, as suggested in the *Chronicle*. 2d. Use the best and most powerful centrifugal pumps to elevate the sands. 3d. Wash the sands for gold as it moves from the boat to the shore. 4th. Make with the debris acres for grain production, thus often turning non-producing lands into producing; and as the State receives all the advantages of the work (1) by taxation on the increased value of all the landed property thus benefited; (2) by the production of gold, which I am satisfied would be no insignificant sum; (3) by the preservation of the hydraulic mining interest, and let the State assume, under certain regulations, the work and its attendant expense, creating reclamation dues upon a just basis to be paid by parties benefited, or sale of State bonds.

As I view the matter, it will not be found so great or expensive a job when once undertaken. With all these later inventions for the handling of immense bodies of earth by machinery, I am not too sure that the rivers will not soon be located and worked for the gold to be obtained by washing. In this event provision should be made to deliver the debris on shore, instead of returning it to the river. That we have in this State both engineering and mechanical skill to accomplish all this work I am quite sure; and in consequence the debris question need not be considered such a "hughear" as to retard gravel mining, frighten the citizens of Marysville, or cause our learned judges to scratch their heads for wise words on the question. These ideas I give for what they are worth, as out of the thoughts of the multitude there may be some good suggestions, for men sometimes "speak wiser than they know." In all our thoughts and movements we must start out with the proposition that hydraulic mining must go on—debris or no debris. To say, or for a moment to think, that this great industry, with its \$100,000,000 of capital invested, and hundreds of millions of prospective production, is to be stopped is simply ridiculous; especially while we are so uncivilized as to use gold and silver as a currency. The abolition of hydraulic mining, and the abolition of the metals as a currency, must be argued together and considered as the same question. If one should go, the other

should. In all this argument I leave out the question of destroying farms away from the river borders by overrunning them with debris, for the reason: Every mining company so doing, by law, is liable and must pay for damages, which is accepted by the miner as justice to this farmer. The real question of controversy and conflict, as I understand it, is the debris of the rivers.

Every good citizen desires to protect the farmer, but in doing justice to him, must do justice to the mining interest as well. We all admit that the farm marks the "higher civilization," while gold is but trash, which the baseness of the age looks into a false god; encompassing, seemingly, all that is wise, virtuous, great and holy. And while it holds such sway, it demands protection.

The effort of both miner and farmer should be to do justice to each other, and devise that plan which advances in interest of both without inflicting a serious injury on either.

ALMARIN B. PAUL.
San Francisco, November, 1879.

Como, Nevada.

EDITORS PRESS:—Your correspondent visited this active little camp on the 12th inst. This is one of the early camps of 1860-62. There was a large town built here at that time, and we are told the population was about 1,000; but the wild excitement and anxiety of the people to make fortunes in a few weeks, together with a lack of experience and want of mills, caused the camp to be abandoned to the lonely solitude, in which it reposed until last spring, when the Eureka boys commenced to prospect one of the old holes, now called the Eureka, which seems to be a nice location. Free gold and silver sulphate can be seen in the rock. There are about 220 tons of ore on the dump. We were informed that the average assay was \$60. Silver and gold specimens from the mine have assayed up in the thousands. The West Rapid is down 175 feet; incline shaft with good ore in sight. The Jacket is down 48 feet; still cleaning out old works. The Chieftain is another good lodge. It is worked by an incorporated company. They are now down 200 feet and have a two-compartment shaft nicely timbered. At present erecting a whim.

There are several other good lodes in the district. A snow storm raging at the time prevented us from examining them. The citizens are composed of the hardy class of early pioneers that know no such word as fail. There are about 120 men in the camp, all being at work. One lodging-house, one livery stable, one saloon and one hotel comprise the business houses of the town. Mr. Wm. Rose is local surveyor, and will soon have a blacksmith shop in connection with his business. Mrs. Ely and her two daughters are the only white ladies in camp. Every one here is hopeful of Como's future. At Palmyra, a mile from here, Mr. A. Welton is building a 10-stamp mill to treat ore by wet crushing and raw amalgamation in iron pans. The mill will be in operation by the 25th inst. If it prove a success in working the ore it will infuse greater life into the camp.

There is at present no small amount of speculation going on in the purchase of town lots and interests in the mines. There is no doubt whatever but Como will have a large active population before spring opens. Wood is plentiful at \$4 to \$6 per cord. There is good healthy spring water for domestic purposes in the town location. Everything has the appearance of health and prosperity in and about the camp.

T. H. M.

THE DEEPEST WELL IN THE WORLD.—The sinking of the deep artesian well near Budapest, Hungary, is now completed; the works were commenced as far back as 1868, and during their progress many interesting facts relating to geology and underground temperature have been brought to light. The total depth is 3,200 feet, and the temperature of the water it yields is nearly 165° Fahr. The temperature of the mud brought up by the borer was taken every day, and was found to increase rapidly, in spite of the loss of heat during its ascent, down to a depth of 2,300 to 2,700 feet. Beyond this point the increase was not so marked. At a depth of 3,000 feet the temperature was 177° Fahr., giving an average increase of 1 for every 23 feet bored. Water first commenced to well up at a depth of 3,070 feet; here its temperature was 110° Fahr., and from this point onward it rapidly increased both in quantity and temperature. Thus, at 3,092 feet, its temperature had already risen to 150° Fahr., and the yield in 24 hours from 9,500 to 44,000 gallons. Finally, when the boring had reached 3,200 feet, at which point it was stopped, the temperature of the water, as it burst from the orifice of the tube, was 165° Fahr., and the volumetric yield 272,000 gallons in the 24 hours. This yield was afterward reduced to 167,200 gallons, in consequence of the bore being lined with wooden tubes, which reduced its diameter. The water obtained disengages carbonic acid in abundance, and also contains nitrogen and a little sulphuretted hydrogen, and 80 grains per gallon of fixed matters, chiefly sulphates and carbonate of potash, soda, lime and magnesia.

The Board of Managers of the Produce Exchange, of New York, have refused to grant the request of the grain dealers to drop the central system, and the system goes into effect Jan. 1st.

Sonora, Mexico.

So much is said about the State of Sonora in Mexico, that we may be pardoned for publishing the following account of it taken from the *St. Louis Globe-Democrat*. The famous old *De Bow's Review* has been revived, and we have before us the first number of the new series. In it is the first translation from Spanish into English of a work upon the geography and statistics of Sonora, published four years ago in the City of Mexico. The origin of the first inhabitants is lost in the obscurity of ages, and the richest and most prolific imagination loses itself in the confusion of conjectures, more or less well founded, regarding the condition of the numerous and diverse tribes, which formerly inhabited this soil, so favored by the hand of the Creator. This portion of the Mexican territory was discovered by a subject of Spain in 1539. Upon his report an expedition to explore the country was fitted out, at an expense of over \$650,000, but it was unsuccessful. Between the date of this failure and 1596, four other attempts at the conquest of the country were undertaken, at an aggregate cost of \$9,240,000. Like the first invasion, they resulted in failure.

During the subsequent 150 years, the Jesuits, by means of missions, succeeded in converting Sonora into a theocracy, comprising 66 towns, governed by 24 missionaries. In 1824, after many internal wars and rebellions, Sonora and Sinaloa became a free and independent State, as regarded its domestic government. In 1839 these were divided and Sonora became an independent commonwealth, extending from 26° 39' 41" to 32° 25' north latitude, and from 9° 19' to 15° 49' 52" longitude west of the meridian of Mexico, and bounded north by the United States.

The climate of Sonora is rather hot than temperate, although in the central and northern portions sharp winds blow and snow sometimes falls. The chief malady is small-pox, which is seldom epidemic. The prevailing winds are very pure, and there are no marshy lands or stagnant waters. The medium duration of life among the natives is from 70 to 75 years, and among those not born there it is from 60 to 65 years; but there are many cases of life much more prolonged. Wheat, maize and most of the American vegetables are produced abundantly in this soil. Of fruits there are oranges and lemons, both sweet and sour, peaches, pears, figs, pineapples, coconuts, limes, dates, bananas, and many others.

There may be counted more than a thousand indigenous plants known to the natives which contribute to the cure of the various diseases, some of which are the true antidotes against the bites of poisonous insects and reptiles. Besides many kinds of timber common to the northern latitudes, Sonora grows in abundance Brazil-wood, sandal-wood, balsam, rose, ebony, mahogany and aloe. Cotton is raised, although not until the seed has been two years in the ground. It is liable to be destroyed by an insect which attacks the root. Rivers, large and small, cross the country in every direction. In the excellent and nutritious pastures of the beautiful valleys, mules, cattle, swine, sheep and horses grow rapidly and increase abundantly.

Wild sheep, deer, wild boar, bear, the Mexican bull and buffalo are found in different parts of Sonora, while the otter, the water-dog, beaver, crocodile and alligator frequent one or the other of its various streams. The lion, leopard, tiger, panther and other wild beasts roam its forests. Vipers, centipedes and tarantulas are among its reptiles. Salmon, shrimp, trout and other exquisite fish abound. On its coast occur pearl-diving, and white coral and ambergris are gathered.

The eastern portion of Sonora comprises the grand range of the Sierra Madre mountains, on whose elevated summits and sloping sides tower huge pines, beautiful firs and odiferous cedars (common and those of Lebanon), which, mingling with vigorous live-oaks and the mighty Druid oaks, form gigantic groups of silent spectators contemplating the grandeur of the harsaltic rocks, the perfection of the marbles and porphyry, the extraordinary magnitude of the grains of gold, and the enormous masses of virgin silver, found almost on the surface of the earth, to compensate the toil and labor of those who seek, in occupation without degradation, the gifts which prodigal nature lavishes upon her sons.

TIN OXIDIZED BY CHARCOAL.—At the American Sanitary Association a block-tin tube was recently exhibited by Mr. J. W. Osborne, of Washington. The tube had been used in the construction of a filter for household purposes. It formed one leg of a syphon, and passed through a stratum of charcoal and one of pure sand, the water to be filtered rising high above the latter. The tube had been extensively used for 20 months, and the outside portion, which corresponded in position to that of the sand, was deeply pitted, oxide of tin having formed. This phenomenon could not be explained, though it was much debated.

A DISPATCH from Singapore says the king of Siam has sent the decoration of "The Golden Flower of Siam" to Hon. Thaddeus Fairbanks, inventor of the platform scales. This is the first time this distinction has ever been conferred on an American.

The plan of having municipalities conduct their own gas works is gaining friends in England. The city of Manchester, during its last financial year realized a net profit of \$470,000 from the gas works which it owns.

MECHANICAL PROGRESS.

Frelman's Ejector.

The ejector is not only very simple, but one of the most effective machines within recognized limits, for raising water and conveying liquids rapidly and economically by steam, that has yet been invented, and in many instances the only one that can properly do the work.

It is applicable in a great variety of forms for raising water and other fluids from tanks, wells, ponds, mines, quarries, holds of vessels, docks, gas works, wheel pits, and it is also well adapted for conveying liquids, of various degrees of consistency, from tank to tank or floor to floor in breweries, chemical works, distilleries, sugar refineries, and other similar establishments.

In outward appearance the ejector is a cylinder of irregular form, varying in length from six inches to three feet, according to size and capacity, and in circumference proportionately to its length. There are three apertures in each machine, one for steam, one for suction, and one for discharge, that which admits steam being much smaller than either of the other two.

In its internal construction this ejector is provided with a series of intermediate nozzles or cones, firmly fitted to the body of the ejector, by which the water from the suction pipe is admitted to the receiving chamber in successive streams.

The great utility of this arrangement (which is the vital principle of the ejector) lies just here. In the ejector the steam jet acts at first only on that portion of the incoming water which is admitted through the first nozzle or cone, so that only a comparatively small jet of steam is required to move it. This stream, propelled by the force of the steam, gives an impetus to the water entering through the second cone, and that in turn becomes a motor to the next, and so on until the last is reached. The water or liquid, accelerated in its passage through these successive nozzles or cones, as well by the force already described as by the vacuum always formed under such conditions, is carried with great velocity through the diverging pipe, with all the force and rapidity necessary to convey it to its required destination.

As a means of ejecting water in sinking shafts and crosscutting drifts these ejectors are valuable, as they can be adjusted to the work, as it progresses, by simply lengthening the piping, the slow process of keeping the water free by means of buckets or bailing out being thus dispensed with.

These ejectors are made in different ways for different purposes, but all equally simple in arrangement. We understand that Nathan & Dreyfus, 108 Liberty street, New York city, are in possession of full information on this subject.

HEAT OF CARBONS IN ELECTRIC LIGHT.—The temperature of carbons giving the electric light has been examined by M. Rossetti, by means of a thermopile, the face of which is placed at a suitable distance to receive rays from a radiating surface of determinate size; the thermal effect being measured by a sensitive reflecting galvanometer. He comes to the conclusions that—1. The positive pole has higher temperature than the negative. 2. The temperatures vary according to the intensity of the current. 3. They are higher, the smaller the radiating surfaces, provided it comprises the extreme point. 4. In the negative pole the minimum temperature was 1,910° Cent., with a large radiating surface of small brilliancy; the maximum 2,532° Cent., the radiating surface being half the preceding. 5. For the positive pole the minimum temperature was 2,312°, the carbon being large; the maximum 3,200°, with a thin carbon and small radiating surface.

THE SWIFTEST SHIP IN THE WORLD.—A new British war vessel called the *Mercury*, built of steel, has just been completed and successfully tried at Portsmouth, England. The vessel is 300 feet long, 46 feet beam, 16 feet 3 inches hold; displacement, 3,750 tons. On her late trial trip the engines developed 7,595 horsepower, and the speed attained was within a trifle of 22 miles an hour. These are remarkable results for a vessel of the dimensions given. The *Mercury* has twin screws driven by separate engines arranged in separate engine-rooms. Her machinery nearly fills the hull. There are 12 boilers; 4 high-pressure cylinders, 75 inches diameter; stroke, 3 feet; boiler pressure 60 to 65 pounds, coal consumed, 2.35 pounds per hour, per horsepower. One man governs the rudder, which is worked by steam. The vessel's armament will consist of 10 64-pounders.

THE ELECTRIC HOSE.—A new thing in fire apparatus is the electric hose. A wire runs along in the cotton or rubber part of the hose, continuing the connection as each section is attached, and over this passes electricity generated by one of the engine's fly-wheels. Connected with the nozzle is a little contrivance by which the engineer can be told, although square distant from the man who is playing water on a fire, to turn her on, cut her off, stop, or go ahead, or anything else that can be agreed upon by a signal which is struck on a gong on the engine.

PATENT FASTENER FOR MACHINERY.—The importance of properly securing all machinery to the estate of the individual or firm to whom it ostensibly belongs has been demonstrated in many instances. Numerous cases have occurred within the last few years where valuable machinery has, under the existing law in England, passed out of the hands of its proper owners into the absolute possession of the landlord of the freehold, or, in the case of the failure of a manufacturer or of a firm of manufacturers, a considerable portion of the plant has become lost to the debtor's estate by reason of its being attached to the freehold in the usual manner. A simple and effective means is now, however, available by which looms and other machinery may be securely fixed down to the floors of rooms in mills or elsewhere, while rendering the machinery as portable from the freehold, and consequently not liable to be claimed by either landlord or mortgagees as fixtures. The contrivance to which we refer is the patent shoe of Messrs. Bentley and Ackroyd, of Bradford. It consists of a single iron casting and of a loose plate or cover, which can be attached to the broad part of the shoe by means of two screws at each end. In order to use it the shoe is placed with its flat side upon the floor, so that the two arms lie on each side of the foot of the loom or other machine which is to be fixed, and is firmly fastened down to the floor by a screw. The covering-plate is then placed over the foot of the machine, and screwed down tight to the shoe at each end; a pin is passed through a hole in the middle of the cover, and drops into a corresponding hole in the foot of the machine, in order further to secure it. Thus the only part which is fixed to the floor of the building, and consequently irremovable, is the shoe itself. —*English Exchange.*

AN ELECTRIC SENTINEL.—Those persons who have occasion to cross the Providence railroad on Washington street, at Forest Hill, Boston, have been frequently surprised to hear a heavy gong continually ringing on a danger-signal post close by, while an approaching train is seen or heard; but from three to five minutes after the alarm first sounds a train dashes around the curve and speeds along, while as it leaves the crossing the gong ceases to ring. This crossing signal is part of the system of the Union Electric Signal Company. It is known as the Union Electric Signal, and it is exceedingly simple. By this system electricity is carried in the rails, holes being drilled in the flanges, into which wire is inserted uniting the points. A one-gravity cell battery is connected by wires to the rails, at the end of a section of one mile, and a signal level upon a post at the other end of the section. Thus the current of electricity is continuous from the battery to the signal. When the train enters upon the section the current is taken upon the wheels and axles, and so being withdrawn from the lever it flies up, and a danger signal is set. So long as the train is on the section, the signal remains set and ringing at "danger" until the gate is dropped. One of the great advantages of the Union system is the fact that a broken rail would break the circuit and at once show the danger. A piece of iron wire laid across the rails breaks the circuit, and the warning is given at the signal. Only a day or two since a stray goat dragged a small iron chain across the Providence road nearly half a mile above the Forest Hill crossing, and while the chain was passing over the rails the circuit was cut, the danger-bell rung, and the danger signal was set at the station. —*Boston Advertiser.*

APPLICATION OF ELECTRICAL POWER TO AGRICULTURE.—A short time since, an experiment was tried by M. Menier, in Nes Park, at Noyelles, on the banks of the Marne, near Paris. A part of the water-power which is used for the workshop operates eight Gramme machines, producing an electric current for the Serrin lamps or Jablochhoff candles. The current from two of these machines was sent into the park a distance of 2,275 feet, where two other machines had been arranged on a truck, and connected with a plow by a rope. A number of furrows were then traced with this single apparatus, and the work thus performed was found to be equal to that of four oxen. The experiment was so successful that M. Menier intends devoting a water-power of 30 horses to agricultural work by means of electric currents. Water pipes will be used for placing the insulated copper wires; and M. Menier expects to be able to conduct his power to a distance of about three miles from his mill in every direction, and by this means to perform various agricultural operations.

NICKEL BRONZE.—At the Exhibition of Applied Sciences, now open in Paris, one of the most brilliant exhibits there is made by the company which owns M. Garnier's patents for the preparation of nickel bronze (white bronze). This remarkable alloy, as manipulated according to M. Garnier's processes, is found to be as capable of application in the art as copper itself. The articles exhibited, which comprise cast, drawn, hammered and engraved goods, have been prepared with the appliances used in the working of copper, and not by one house, but by several firms. The alloy does not rust, takes a brilliant polish, and is not dearer than plated copper, while its substance is, of course, uniform throughout its thickness. For builders' fittings, harness, chains, arms, scientific instruments, clocks, art metal work, etc., the new alloy seems to be of particular value.

PHOTOGRAPHS ON SILK.—One of the silk-manufacturing firms of Lyons is introducing the production of photographic impressions on stuffs. They sent to a recent meeting of the Photographic Society several pieces of silk with a variety of photographic pictures printed thereon, including, among others, a number of large medallions representing pictures of the old masters. The length of the specimens thus exhibited is stated as being no less than 131 feet.

SCIENTIFIC PROGRESS.

Iron and Steel in the Arts.

The earliest mention of iron is found in the Book of Genesis, Chap. iv., 22, where we read that Tubal Cain was "an instructor of every artificer in brass (or bronze) and iron." The Hebrew word is *barzel*, from a root signifying hardness and strength. We read also of this iron bedstead of Og, King of Bashan, and of Sisera's 900 chariots of iron, 1,300 years before our era. In the time of Agamemnon iron was not in general use. No implements or weapons of this metal have been found in the remains of Mycenæ or of Troy. A large iron plate, however, has been discovered in one of the Egyptian pyramids. In the time of Homer iron was a rare and costly commodity, more highly prized than gold. The poet never mentions it as the material of armor or weapons, which were entirely of bronze, but in two passages of the *Iliad* iron axes are mentioned as valuable prizes in the athletic games.

Iron was not employed for weapons by the Romans before the time of Hannibal in the second Punic war, but once adopted, the practical genius of the Roman people perceived its advantages, and entered upon its manufacture with avidity. It is not probable that either the Greeks or Asiatics knew the process of extracting iron from the ore. Both iron and steel are found occasionally in a native condition, principally of meteoric origin. Hence it is supposed originated the Greek name for iron, from the same root as *sidus*, the Latin for the starry heavens. The Romans in Britain practiced the art of extracting the metal from the ore on a large scale. Their works were principally carried on in what is now the Forest of Dean in Gloucestershire, and that of Anderida in Sussex, in both of which enormous quantities of scoria and cinders have been found. With imperfect methods they were unable to fuse the ore so as to produce cast-iron, and it is probable that the metal was refined by several processes before it was finally adopted for use. The mines had been previously worked, for Cæsar on his arrival found the Britons in possession of iron, though it was employed more for ornament than use.

This imperfect method continued down to the sixteenth century, when the introduction of the blast furnace led to the production of cast-iron, the manufacture of which was for a long time principally supplied from the scoria and cinder heaps left by the Romans.

Once adopted, the superiority of iron over every other metal for tools and implements led to the supersession of all other materials for that purpose, and the use of iron entered upon a progressive career, which has extended with the advance of society in an ever-increasing ratio. One of the first purposes to which iron was applied was that of weapons and armor, the manufacture of which attained in the Middle Ages a very high degree of excellence; the hauberks of chain mail of the most intricate and delicate patterns, the chased and inlaid suits of armor, constantly changing its form, exercised the ingenuity of the armorers, and exhibit in the remains left to us a large amount of ingenuity and artistic skill. Offensive weapons were equally elaborated. The Toledo rapier and the Damascus scimitar had a world-wide reputation, and even in England the Sheffield *thwistle* in the time of Chaucer had become famous for its quality. Iron work at this period was of the most elaborate description. The locks and keys, the hinges and bolts, the smith's work in gates and screens, exceed in beauty anything of the kind which has since been produced. Many specimens remain both in England and on the Continent, among which may be mentioned the iron-work in the church at St. Gudule at Brussels, the well cover by Quentin Mastys at Antwerp, and, though of a much later date, the beautiful park gates at Hampton Court. The introduction of cast-iron into general use in the seventeenth century effected a considerable change in the application of the metal. Its cheapness led to its extended use in the household economy of daily life; fire grates, stoves, pots and pans, gates, palisades, pipes, etc. This was no doubt in many respects a great advantage, but it had a very injurious effect on the art of the smith, superseding skill and ingenuity by the deadening process of routine in cast work, and substituting cheapness for excellence.

OPTICAL TELEGRAPHY.—The French Minister of War has published a regulation for organizing optical telegraphy in time of peace. The several places on the French frontier are to be connected by posts; apparatus are to be maneuvered by persons trained, who will keep records of communications sent or received. This new service is to be placed under the supervision of the Director of Aerial Communications, who already has command of the balloonists and the colombophiles for carrier pigeons.

The Influence of Silicon on Steel.

An interesting experiment, which shows the effect of silicon in preventing the reduction of phosphorus in acid in the cinder of an open-hearth furnace, is given by M. A. Pourcel, of Terrenois. A three ton charge, containing 250% of carbon and 0.50% of phosphorus was melted in an open-hearth furnace. As soon as the charge was thoroughly melted, the slag which covered the metal was removed, and the surface of the bath laid bare. The gas was then shut off, and the hot air alone allowed to pass through the furnace. At the end of 15 minutes a black slag had formed on the surface of the bath, and during its formation jets of carbonic oxide gas were constantly rising from the metal. This fact should be noticed. Samples of metal and slag were then taken, and the gas again let on to reheat the bath. The phosphorus was estimated in the metal and slag, and the percentage in the former was found constant, viz., 50%, the slag showing no traces of this element. When the bath had been reheated the slag was again removed, the gas shut off, and a second refining effected, as before, but, instead of allowing carbonic oxide to form, an addition was made of a certain quantity of silicic acid of iron manganese, containing 20% manganese and 10% silicon, which completely prevented the disengagement of carbonic oxide gas. After a quarter of an hour the jets of carbonic oxide again appeared, and a sample of the metal was taken before the gas was turned on, and the slag formed during the passage of the air only was removed. The metal now yielded, on analysis, only 0.35% of phosphorus, and a very appreciable amount was found in the slag, although it was not estimated quantitatively. The experiment was repeated, but instead of taking samples immediately on the reappearance of the jets of carbonic oxide after the action of the silicic acid, and instead of clearing away the slag formed during this period, which slag contained the phosphorus that had been scorified, samples were not taken until 15 minutes after the gas was turned on and boiling of the bath had recommenced. It was now found that the phosphorus had disappeared entirely from the slag, and had been reabsorbed by the metal, which yielded, on analysis, its original content, viz., 0.50%. Thus, under the oxidizing action of a current of hot air, phosphide of iron is scorified, when the reducing action of carbonic oxide is obviated by the addition of a metallic silicic acid to the bath. By making three successive calculations, each of from 10 to 20 minutes' duration, and under the above-mentioned conditions, M. Pourcel succeeded in reducing the phosphorus from 0.5% to 0.24%.

NEW SPECIES OF FISH.—At a recent meeting of the Christiana Society of Sciences, Robert Collitt stated that the deep-water fishes collected during the last Arctic expedition amounted to 33 species, and proved to be of great interest to science, as the fish had, with a few exceptions, been taken from depths from which no Arctic fishes had previously been obtained. The apparatus employed was the so-called trawl-net, constructed on the same principle as that employed by the English fishermen at Doggerbank. Fish were taken up with that apparatus from depths of 1,400 and 1,500 fathoms. Five species prove to be entirely new to science, and it was necessary to classify one of them under a new genus. This was caught at a depth of 1,200 fathoms, and was about one foot long. While alive, it was beautifully rose-colored all over, but of so soft and gelatinous a substance that it was half transparent, and the heart could be seen performing its functions; and a large portion of the brain, the entrails and the whole backbones were visible through the skin. The abdominal fins were transformed into two long split threads, which gave the fish a very peculiar appearance. It was named *Rhodichthys regina*, and belongs to a group of the genus deep-water fishes which is chiefly limited to the tropic seas.

A MAMMOTH.—A short time ago, says the *Marysville Appeal*, parties employed on levee work about one mile above Yuba City, and near the west bank of the Feather river, discovered portions of the remains of some huge animal, supposed by the laborers to be the bones of another mastodon. Parties subsequently examining the same conclude the fragments of bones exhumed were once those of an elephant. The bones were found imbedded in hard pan, and about three feet below the soil removed. The animal was imbedded in a standing position. The parts exhumed include two large teeth, weighing 4½ pounds each; the upper joint of one of the hind legs, measuring four feet six inches; a portion of the skull and a socket of a limb joint. The formation of the teeth classify the animal among the elephant class. It is expected that the entire frame will be exhumed, but considerably broken.

ORIGIN OF PETROLEUM.—One of the latest hypotheses of the origin of petroleum is that advanced by M. Mendelejeff. Starting with the nebular hypothesis, he regards the interior of the earth as metallic, doubtless composed largely of iron and carbide of iron; through rents made by earthquakes, water gained access to these bodies at a high temperature and under great pressure, and by their mutual chemical action, metallic oxides and saturated hydrocarbons resulted. It is these latter, according to M. Mendelejeff, that carried by watery vapor, have made their way through the overlying rocks.

A Strange Arctic Region.

Whether the success of Prof. Nordenskjöld in his voyage from ocean to ocean in the Arctic regions will ever be productive of commercial results or not, cannot now be determined. The discoveries made by him will, however, command the attention of scientific men, and perhaps be the means of solving many problems connected with the violent disturbances that have afflicted the globe and changed climates as well as the flora and fauna thereof.

When the ice closed in upon the *Vega*, and left the stout ship ensnared in those northern solitudes, Prof. Nordenskjöld wrote a letter to Dr. Oscar Dickson, the main contributor toward the fitting out of this expedition, describing the scenes along the coast. The letter dispatched on the 20th of February, has at last reached its destination, and is now published in the *London Standard*. The letter calls attention, in the first place, to a group of islands which are very remarkable in a scientific point of view. These islands, the new Siberian, open this book of the history of the world at a new place. The ground there is strewn with wonderful fossils. Whole hills are covered with the bones of the mammoth, rhinoceros, horses, ur, bison, oxen, sheep, etc. The sea washes up ivory upon the shores. In this group is possibly to be found the solution of the question of the ancestry of the Indian elephant, and important facts with regard to the vertebrates which existed at the time of man's first appearance on earth. How came horses and sheep in a region now locked in the fetters of an eternal winter, uninhabited by men, not now supporting animal life in any form, and almost impossible of access? Prof. Nordenskjöld was unable to solve the question himself, and he suggests that it is of the utmost importance to science to send a light draft steel steamer to those islands for a thorough exploration.

The new tribe of Indians found there, the Tschuktschi, are on the original highway between the cradle of the human race and the home of the aborigines of the northern part of North America, and it is not thought that the resemblance between them and the Greenlanders is accidental. The arrival of the *Vega* on the Tschuktschi coast was an event like the landing of Columbus in the new world. It was an unprecedented occurrence, and made a sensation throughout the region.

East of the Lena, Prof. Nordenskjöld found on shore no scattered blocks of stone such as are distributed over a continent by glaciers and such as are found elsewhere in Siberia. This fact was held to point to the absence of land out to sea north of that coast, and it excites anticipations as to the possible discoveries which are to be made by the *Jennette*. Not the least of the peculiarities of this strange region is the fact that the coast appears to be rising slowly out of the sea. The inhabitants have to shift their villages at times nearer to this water, which is gradually receding from them.

Shipping Laws of the United States.

Under the head of "The Miserable Shipping Laws of the United States," the *New York Mail* makes additional comments upon an article in the *Philadelphia Record*. It is difficult to conceive of any grave reason why this country should not become the mistress of the seas, at least so far as the carrying trade is concerned. Evidently the only obstacle in the way is our own Government. We cannot say that there is a lack of common sense in not investigating this matter, but we may say that there is a lack of attention to the demands of the country for legal provisions which will advance its welfare. There never was such an opportunity for the United States to arrive at a legitimate superiority in the shipping trade, and if no attention is paid to the matter now, a future generation will point to the "possibilities," the "might have been" of blundering statesmen. We speak of progress, and our progress is more in talk than in action. Many of our laws are wholly inadequate for the development of the country, and yet they remain unchanged to the detriment of our greatest interests.

Speaking of the laws which prevent Americans from becoming ship owners, the *Philadelphia Record* says:

"Thus have we presented the anomalous spectacle of a people languishing in the over-productions of their own industries, unable to build ships, forbidden to buy them, and compelled to await the coming and going of foreign fleets and foreign merchants to develop a foreign trade which, to a large extent, is 'second hand.'"

To fully understand the meaning of the *Record*, we must notice what some of the provisions of the laws governing American ships are: An American can buy a foreign ship, but cannot have it registered in the United States. If an American resides in a foreign country, his ship, though built in the United States, forfeit their registry during their owner's absence, unless he is a consul or is connected with some house composed entirely of Americans. An American cannot sell half his ship to a foreigner without the ship forfeiting its registry. An American cannot have a ship registered when it is built in this country if he has a foreign partner. If a naturalized citizen goes abroad two years, every ship in which he owns the smallest interest forfeits its registry. In the meantime, iron steamships have well-nigh driven wooden

ships from the sea. Plenty of first-class iron steamers are for sale in English and Scottish ports which American merchants would like to purchase, but our laws will not permit. It is times all those laws were stricken out, and the same freedom given Americans who may wish to purchase foreign ships that is given those who wish to buy a horse or a suit of clothes abroad. The laws were framed when the United States among powers was one of the weakest; they do not apply any longer. Half the profits to be derived from the food crops of the United States, when sent abroad, goes to the steamship companies which carry the freight to Europe. The *Record* estimates that a ship costing \$250,000 will earn, running between the United States and Europe with cargoes one way, \$2,224,000 in her natural lifetime of 20 years. This, too, only reckons freight at \$6.50 per ton. From these figures it is easy to see that foreign ship owners are making as much from our harvests as the men who till the soil on which the harvests are planted. Then all the foreign commerce of the United States except a trifle is carried in British and German ships. And this is the case, too, when foreign markets are the great need of American manufacturers. Still, those obsolete laws are kept in force though our shipyards are idle and the men who were sailors in the old days of wooden ships are seeking other occupations on shore. If Congress were to try to prevent a State from selling its products, the people would raze the capitol to the ground. Yet they keep in force, year after year, laws which in effect say, "Half the profits of all the products you desire to send abroad must be paid to foreign ship owners." Is it not time that such laws were wiped out?

Mining Decisions.

In a recent number of the *Salt Lake Tribune*, "Pablo," in his regular letter from Washington, refers to the following points decided under the mining laws, in regard to placer claims.

Acting Commissioner Armstrong, of the General Land Office, replies to a letter of inquiry: That since the act of July 9th, 1870, it has been continuously the practice in the Land Department to recognize the right of an applicant for patent for placer land to embrace in his application survey, entry, and patent, two or more original contiguous locations held by him by purchase, although exceeding in the aggregate 160 acres in area; such original location being in conformity with law.

The protest of Geo. W. Hall, et al., Central City, Colorado, against mineral entry No. 1129, has to-day been dismissed and the original entry approved for patent when reached in its regular order.

This protest has attracted considerable attention in mining circles. It was made on the 15th of March last, against allowing the entry of the Hunter lode and mill-site. The entry—lot 826, A and B, was made March 20th, 1879, by the Equator Mining and Smelting Company. The protest, supported by several affidavits, is based substantially upon allegations that the Hunter lode is located on the side of a mountain immediately below certain patented claims which have used the land embraced in the Hunter claims for several years as dumping ground; that the claims are so situated that in the due course of mining it is necessary to throw large quantities of debris upon said ground; that there is no vein or lode, or valuable deposit of minerals at the discovery shaft of the Hunter lode, and that no vein or lode has been discovered within the limits as required by section 2320, U. S. Revised Statutes.

The Equator Company file affidavits alleging the existence of a well-defined crevice of mineral-bearing rocks in said discovery shaft; it is also alleged under oath that on the western portion of said claim large quantities of valuable silver ore have been taken out, the mine at the point being worked at a depth of 360 feet from the surface.

The Hunter claim intersects other valuable claims; the locality is undoubtedly mineral, and no presumption exists that the land is non-mineral.

Mr. Armstrong, the Acting Commissioner, says in view of all these facts: "I regard the proof of discovery of a vein or lode, prior to location, as satisfactory. The fact that the claim has been used as dumping ground, and is convenient for such purposes constitutes no objection whatever to its location and entry. It is conceded to be public land to which no adverse claim has ever attached. It is shown to be mineral land, properly located and it will be patented when reached. No valid objections appear to the mill-sites."

In consequence of a law in Oregon providing that but 300 feet in length can be located on a lode or claim, the General Land Office makes the following statement: Section 2320 of the U. S. R. S. provides that: "A mining claim located after the 10th day of May, 1872, whether located by one or more persons, may equal, but shall not exceed 1,500 feet along the vein or lode," and no authority to restrict such length is delegated to any State, Territory or mining district organization. By the same section it is permitted the organization named to fix the width of lode claims with the restriction that no greater width than 300 feet on each side taken nor the width limited less than 25 feet on each side of the middle of the vein.

The Oregon law, therefore, is in conflict with the express authority of the United States Statutes, and has no effect in determining the rights of a locator.

The Boom in the Lumber Interest.

We know of nowhere that a "boom" can be more properly placed than in saw-logs and their resultant products. At all events there is a boom, and during the last week, there has been an advance of about \$4 per thousand in "rough redwood," and a corresponding appreciation in finished lumber. This is the direct result of the better feeling which has crept into all our industries and in sympathy with the advance in other building materials. There has been an advance all along the line of builders' supplies, and those who have been intending to build during the cheap times, but have thus far failed to place their contracts, may now add perhaps 20% to former estimates.

It is a peculiar and yet a clearly intelligible disposition of the public, to refrain from using building materials when they are at a very low mark. Such low values are of course incident upon a slack demand, and the slack demand is the product of "dull times." It takes an amount of heroism to build as an investment simply because one can build cheaply, and such heroic action is seldom indulged in. When lack of confidence is general, few are strong enough in hope to stem the tide. Therefore while building material has been at bedrock prices, there has been but little building except such as was done for present use, or immediate sale to users. And now with affairs looking up and a general tone of trust in the community, building will revive and the rise in materials will be counted a small objection when the other attendants of investment are so auspicious. We can but hope, however, that our friends who have been long contemplating improvement in their homes and outbuildings, have already carried out their plans, for there will probably be enough new ventures incident upon the return of prosperity, to sustain this better rewards which seem now to be before our vast lumbering interest.

The rise in lumber prices will be heralded with satisfaction in our forest counties, where for a long time the pall of unprofitable production has rested. The axes will ring and the brisk stroke of the "cross cut" will invade the solitary sighing which the woods have long enjoyed. The desolate mills will again warm their boilers, and a host of idle men will rally again in the fragrance of the sawdust. The thriving coast towns of the north will awake from their lethargy and feel the spirit of advancement which they have been long awaiting for, the wharfs will again be covered with lumber awaiting shipment, and the long chutes will be dangerous for those who lay hold upon the hand ropes. Nor will the interior lumber interests be less stimulated. The general result will be most gratifying to those who hold timbered property, to those who labor in the mills, and to all who furnish supplies to a busy people. The lumber-producing interest of our State and of the coast besides is a grand one, and one which is apt to be overlooked by those whose only hint comes from the carload of boards. The coming of better times to the lumbermen means the extension of comforts to many thousands of our citizens, and therefore should be hailed with general satisfaction.—*Pacific Rural Press*.

Relics of the Mound Builders.

During the grading for the Chicago & St. Paul railroad, four miles up the Kankakee river from Wilmington, Illinois, a bank or mound of stiff, clayey sand, about forty feet in diameter and ten feet in height, was cut into by the graders, and skeletons, pieces of pottery, and copper implements were found. The mound, which is situated near Forked creek, about a mile east of the Kankakee, is very compact, and is known generally as Smith's Indian Mound. The skeletons which have been unearthed are in a poor state of preservation, the largest and hardest bones only being found; and, by comparing their condition with that of bones found in a similar soil and latitude, whose ages have been determined, the only conclusion to be arrived at is, that these are those of the Mound Builders, and were placed in the ground over 2,000 years ago. On each side of the head of the skeletons, near where the ears were, were found pieces of copper about an inch and a half in thickness, and these, it is supposed, were used as ear-ornaments or ear-rings by the ancient owners of the skulls. They are well-shaped and have a circumference greater than that of the average skull of the present day. By the length of the thighbones it is judged that these aborigines must have been fully six feet in height, and some of them are probably seven feet. One skull, of twice the size of any of the others found, was sent to a gentleman in Chicago.

By the side of the skeleton (or rather where the skeleton was) belonging to this skull was found a large kettle containing several flint arrow-heads and a copper blade. The blade is about four inches in length and half an inch in thickness, tapering towards the edge from the center. It is now in the possession of Frank Larned, of Wilmington. As Lake Superior is the nearest point from which copper can be obtained, this metal was probably brought from the Gulf of Mexico. The vases seem to have been made of pounded shells mixed with blue clay. Some of the vases are ornamented by scroll work, nearly the same as the engravings on the outside of water-cases, and others by fancy but regular indentures. Dr. E. R.

Willard has in his possession one, about five inches in its greatest diameter, four inches high, and four inches through the top, with places on the sides showing where the handles had been. Most of the skeletons are found at a depth of five or six feet, lying face downward, with the head toward the northwest. Pieces of burnt red clay, varying in shape and size, and placed about eight inches apart, surround the skeletons.

A Practical Calculating Machine.

The arithmometer or calculating machine, of M. Thomas, of Colmar, was invented in 1820. Since then it has undergone many improvements at the hands of the inventor and lately of his son, M. Thomas de Bojano, so that it is now offered in a form which M. Sebert, in a recent report to the Paris Societe d'Encouragement, pronounces to be thoroughly adapted for practical use. The machine performs all ordinary arithmetical operations, comprising the extraction of roots. Among the more important recent improvements (for details of which we must refer to the *Bulletin* of the society just named), is the counter of the number of turns of the motor handle, and the automatic inscription of successive figures of results, in divisions and extractions of roots, and of multipliers and multiplications, relieving the mind of the operator greatly. An idea of the progress of the machine, may be had from the fact that the product of the number 99,999,999 by itself, is formed by the new machine in 24 seconds; it took nearly a minute in 1851. The new machine can also go beyond the former in giving the product of the number formed of ten nines by itself, which it does in 25 seconds. The product of the number formed of eight nines by this number formed of eight fives is now obtained in 17 seconds, as against about 45 seconds in 1851. Processes of addition alone are not performed much more quickly than by an expert calculator, but mental fatigue is at least saved. This machine is well adapted for complex operations, as in calculations of algebraic formulae for ordinary calculations relative to constructions, cubages, estimates, etc., for calculation of formulae into which trigonometrical values enter, and here it allows of dispensing with the use of logarithms, tables of natural trigonometrical lines being used. In construction of tables of multiplication, ready reckoners, etc., the machine gives results that are truly marvelous. The popularization of the machine has been slow, but (with removal of imperfections) has considerably improved, as the following figures show: In the 44 years, from 1821 to 1865, only 500 machines were sold; in the 13 years, from 1865 to 1878, 1,000, viz., 300 in the five years, 1865 to 1870, 400 from 1870 to 1875, and 300 from 1875 to 1878, or 100 a year. Of the latter number about three-fourths are six-figure machine, six-tenths eight-figure, and only one-tenth ten-figure. Of 100 machines sold, 60 go abroad and only 40 remain in France. Among other establishments in France which use the machine may be mentioned the Magasins du Louvre, the Compagnie des Petites Voitures, the offices of the Artillery Service, Assurance and Railway companies, the Observatory, the Ecole Polytechnique, and Creusot. It is estimated that a machine will work daily for ten years before requiring repair; and from the nature of the component parts repair is easy. The price is rather high, 500 fr. for a six-figure machine; and M. Sebert is of opinion, considering how largely the manufacture involves the easy repetition of similar pieces, that this might be so organized as to supply the machines at half the present price.—*Iron*.

THE MICROSCOPE IN THE WITNESS BOX.—As the *New York Tribune* says, the scientific aspects of the evidence against the Rev. Mr. Hayden, of Madison, Conn., for the murder of Mary Stannard, are truly remarkable; indeed the microscopic exhibition of arsenic and the comparison of arsenical crystals show that the law has a powerful auxiliary in chemistry. After the arrest of Mr. Hayden, and the disinterment of the remains of the dead girl for examination, it was claimed that all of the arsenic which Hayden had bought was still in a box in the barn. There a box was found containing a full ounce. It was shown that the arsenic found in Mary Stannard's stomach could not have been taken from this box. At this point recourse by the prosecution was had to Prof. Dana, who visited England, studied the manufacture of arsenic, and then, by the use of his microscope on the crystals, demonstrated that the arsenic from the girl's stomach was an entirely different lot from that hidden in the barn, and that it was identical with the arsenic sold by Tyler, at the time when Hayden is known to have bought his ounce. The conclusion sought to be established is that a part of the arsenic bought by Hayden was used to poison the girl, and that the rest was flung away, and that the barn arsenic was bought elsewhere afterward merely as a blind. The crystals of the stomach arsenic are three or four times as large as those of the barn arsenic, but none of them are large enough to be visible without the microscope. Hereafter criminals will do well to recognize in science one of the agents of possible detection.

THERE was an increase in the national bank circulation for October of \$3,500,000. The demand is steadily increasing, and the indications are that more will be taken out during the coming month than for any preceding month in several years.

Influence of Planetary Movements.

It has been assumed by certain *soi disant* scientific observers, that terrible troubles are to be brought upon the earth by this planetary movements occurring between 1880 and 1887. The assertions that calamities are to afflict the air, land and water, have been so often repeated, and so much rhetorical flourishing has been indulged in the description of the dreadful evils to come, that many people have ceased to argue the matter, and have settled down into that calm belief which accompanies the apprehension of the inevitable. Prof. R. A. Proctor, however, is not of those who have been frightened at the predicted disasters, and goes into the merits of the thing in the following vigorous style:

"Whether the American 'professor' who announces these coming troubles is in any way related to the New York astrologer who wants money for calculating the planets, I do not know. But certainly they play into each other's hands. To say the truth, as the *Athenaeum* recently pointed out, astrology has been looking up of late; a mischievous result of the theories which have been recently propounded respecting the influence of sun-spots on the weather, commerce and other matters—theories notoriously propounded in the first instance in order to obtain money from Government for certain greedy scientists, who were to watch the sun for us, and promised all manner of good things when once the money had been advanced. I do not think the Government is very likely to waste any money over such experiments, and, indeed, the Physical Observatories advocates have latterly been far less noisy than of yore, feeling, perhaps, that they have shown their hand somewhat prematurely. But much mischief of another kind has resulted. Because these persons, and some who innocently enough had joined them, assert that sun-spots affect terrestrial relations in certain definite and ascertainable ways (for which statement there is not a particle of valid proof), and because it is supposed that the planets affect the sun-spots (for which supposition also there is no evidence whatever, but very strong evidence against it), we are to believe that, after all, the old astrologers were right, and the planets influence the fates and futures of men, not directly, but still effectively, though indirectly. Of course even the advocates of sun-spot influence and the believers in planetary power to generate sun-spots would reject this preposterous inference. But it finds acceptance among the ignorant; and those rascals who are always on the watch to find new ways of swindling the public, take advantage of the fact. It ought not to be necessary for me to say a word about the grim tidings announced by the American 'professor,' for they have not a particle of scientific significance. But in so far as such predictions (save the mark!) are based on the idea that the planets influence the sun's photosphere, I may say so much as this, that instead of the giant planets, Jupiter, Saturn, Uranus and Neptune, being the chief solar disturbers, even according to those students of science who maintain this theory, Venus would be and is more powerful than any of those planets, and our earth more powerful than the three outermost of the giant planets. To see this it is only necessary to remember that the tide-raising power of a planet or other orb (that being the nature of the influence assumed according to this theory), does not diminish as the square of the distance increases. Thus, putting Saturn's distance at only 9 instead of 9² (that of the earth as unity), and the mass of Saturn at 90 times the earth's, Saturn's influence would be to the earth's as 90 to the cube of 9, that is as 90 to 729, or less than one-eighth of the earth's. Jupiter would exceed the earth's (roughly) as 300 exceeds the cube of 5, or as 12 exceeds 5; but would be far less than that of Venus. Then, again, the simple conjunctions and oppositions of the most effective planets would be far more effective than the perihelion passage of all the planets. Since we survive the conjunctions of the earth and Venus, we are not likely to perish even though the giant planets should pass their perihelia at about the same time, which, however, never has happened within historic times, and certainly will not happen for many centuries to come."

A LARGE ELECTRO-MAGNET.—Mr. Charles Reitz, of Indianapolis, Ind., sends us a description of a large electro-magnet made by him for Prof. Zahn, of the University of Notre Dame. The length of the cores is 30 inches, diameter 4 inches. Heads, of rubber, one-half inch thick, 9 inches in diameter. The yolk is 3¹/₂ inches thick, 6¹/₂ inches wide, and 18 inches long, with 3-inch slots to admit of moving the cores. The bolts which connect the cores with the yoke are 1¹/₂ inches in diameter. The cores are wound with eight layers of No. 6 cotton-covered copper wire, the wire being wound double, and the alternate layers being provided with terminals, which are connected with a plug switch on the baseboard, so that the electric current may be sent through the coils in various ways. The magnet is provided with two sets of pole extensions for diamagnetic experiments, one set being conical, the other flat. The armature is 15 inches long, 3 inches thick, and 4 inches wide. Different effects may be produced in this magnet by connecting the coils with the battery in different ways. The changes that may be made in this way are almost without number. It is estimated that the magnet, with proper battery power, will lift three tons. The weight of the magnet and its attachments is 800 pounds.

USEFUL INFORMATION.

A New Fluorescent Body.

According to the *Journal of the Chemical Society*, C. O. Harz has discovered a new fluorescent body in *spergulin*. This product occurs in the seed coverings of the Caryophyllaceae plants, *Spergula vulgaris* and *S. maxima* (Anglican "Sparrey"). It is produced at the time when the seeds blacken and are nearly ripe. *Spergulin* is very soluble in absolute and aqueous alcohol. Viewed by transmitted light the solution appears nearly colorless, with a shade of olive-green; by reflected light it exhibits a dark blue fluorescence. It has not yet been obtained in the form of crystals. It is very soluble in methylic alcohol, less so in amylac alcohol, and scarcely soluble in ether or petroleum. Concentrated sulphuric acid dissolves it, forming a dark blue liquid. The fluorescence of an alcoholic solution of *spergulin* is maintained for more than a year if the liquid be kept in darkness, but is rapidly destroyed by the action of direct sunlight, and more slowly by that of diffused light. Small quantities of caustic alkalies, or alkaline carbonates, added to an alcoholic solution of *spergulin*, transform it into an emerald green fluorescent body; and basic lead acetate produces a precipitate. The new compound contains 61.85% of carbon, 7.05% of hydrogen, and 31.8% of oxygen. It appears to be related to chlorophyll, and is probably closely allied to phylloxyanthin. An alcoholic solution of the product showed strong absorption, almost entirely in the violet; and in this respect differs considerably from chlorophyll, phylloxyanthin and phylloxanthin. Mr. Harz is disposed to regard *spergulin* as a feeble acid, the acid salts of which, as well as the acid itself, exhibit blue fluorescence, the neutral salts exhibit green fluorescence, and the basic salts are destitute of fluorescent properties.

HOW BOG OAK ORNAMENTS ARE MADE.—When taken up, Irish bog oak is perfectly black from the action of the peat or bog water. It is very rarely obtained in a sound state, and in most cases the outer portions of the tree or log are rotten and useless even for fuel. When laid up for use, care must be taken that it is not placed in the open air, lest it may, from the sun's rays, become open and shattered into chips from end to end. To preserve it, it must be put into some cool place, and left to dry gradually, and when properly seasoned it must be cut in lengths of from two to four feet, and these lengths be split again, and the sound parts be removed from the unsound. It takes from four to six years to season some specimens, as, in many instances, the wood is found at a depth of eight and sometimes ten feet under the surface. When properly seasoned any portion requiring to be glued becomes hard as stone, and is firmer and less liable to give way than any portion of the manufactured article. The finish is not quite perfect until the article has been for some time in use, and the longer the finer the article seems to be, no matter whether used as a personal or table ornament. The men employed are all without exception, self-taught; each one makes his own tools and will not take any apprentices; and each person has a peculiar taste for certain kind of ornaments, which he follows, and which he is left to produce the best specimens he can. There are jewelers who mount and embellish the ornaments with gold and silver, and with rare and most brilliant Irish gems, such as the Kerry Irish diamond, the emerald, the garnet, amethyst, beryl, aquamarine and Donogal pebble. The Celtic ornaments are generally studded with the above native gems. They are beautiful and most artistically executed.

HOW TO DETERMINE THE QUALITY OF SILK.—A writer in the *Hartford Courant*, speaking of the various kinds of black silk, gives the following directions for detecting the spurious from the genuine article: "Take ten fibers of the filling in any silk, and if on breaking they show a feathery, dry and lack-luster condition, discoloring the fingers in handling, you may at once be sure of the presence of dye and artificial weighting. Or take a small portion of fibers between the thumb and forefinger and gently roll them over and over and you will readily detect in the one the gum, mineral, soap and other ingredients, and the absence of them in the other. A simple but effective test of purity is to burn a small quantity of the fibers; pure silk will instantly crisp leaving only a pure charcoal; heavily dyed silk will smolder, leaving a yellow, greasy ash. If, on the contrary, you break the ten strands and they are of a natural luster and brilliancy, and fail to discolor the fingers at the point of contact, you may be well assured that you have a pure silk, that is honest in its make, durable in its wear."

TO CONVERT AGATES INTO ONYX.—The agates, ground to their proper shape, are allowed to remain during a period of eight days in a solution of iron in aqua regia. Those portions of the stone which are to be made white are dipped for the same time into a solution of equal parts of potash and caustic potassa in water. The articles are then dried and finally hurst in a stone vessel. This process is carried on at Oberstein, Germany, the center of the agate industry of Europe.

TO PREVENT NETS FROM ROTTING.—The following treatment is said to preserve nets for a long time in good condition: Soften one pound good glue in cold water, then dissolve it in ten gallons of hot soft water with one-half pound curd soap. Wash the nets in soft water, then boil them in this for two hours, press out excess of the liquid and hang up over night. The second bath consists of alum 2 pounds, water 5 gallons; heat nearly to boiling, and immerse the nets in this for about three hours, then press and transfer to a strong decoction of oak bark or a solution of sumac in warm water (water 5 gallons, sumac 8 pounds) and let them remain immersed in this for 48 hours, or longer if convenient.

FRUITFULNESS OF A GRAIN OF WHEAT.—If, says a writer in a German contemporary, we reckon that a single grain of wheat produces 50 grains, and that these 50 will each produce 50 grains more, and so on, we find:

In the second year.....	2,500 grains
" third ".....	125,000 "
" sixth ".....	15,625,000,000 "
" twelfth ".....	244,140,625,000,000 "

The third year's crop would give 300 men one meal, leaving enough bran to feed eight pigs for one day. The produce of this single grain in the twelfth year would suffice to supply all the inhabitants of the earth with food during their lifetime.

GRAY PACKING FOR MARINE ENGINES, ETC.—Grind together cleaned Java rubber, 5 lbs.; Para rubber, 25 lbs.; oxide of zinc, 10 lbs.; carbonate of magnesia, 6 lbs.; porcelain or Cornwall clay, 3 lbs.; red lead, 2 lbs.; pure sulphur, 30 ozs. It may be proper to state that good purified Java rubber might be substituted by engineers with good effect for Para rubber in the above and some other compositions.

LIGHT BUFFER SPRINGS.—Grind together clear Java rubber, 25 lbs.; Para rubber, 5 lbs.; common magnesia, 10 lbs.; pure sulphur, 25 ozs. This is brown at first, but in a few days turns gray or white, and just sinks in water. Springs made from this compound, 4¹/₂ x 2¹/₂ x 1, pressed to half an inch, showed 3¹/₂ tons on the dial.

TO PREVENT LEAKAGES.—Make a composition of four pounds resin, one pint linseed oil and one ounce red lead. Apply it hot with a brush to the place where the L joins the main house, or for a dormer window that leaks, or around chimneys. For making water casks tight, it has always proved effectual.

A CHEAP filter can be made from a common garden pot. The hole is plugged with a sponge but not too tightly; a layer of powdered charcoal is put in the pot two inches deep, then a layer of the same quantity of clean sand, and upon that a layer three inches deep of clean coarse gravel.

PAPIER MACHE for small work is made by boiling clippings of paper in water, beating them to a paste, adding glue or gum sizing and pressing into oiled molds.

GOOD HEALTH.

Headache.

A lady asks for a few thoughts on the subject of the headache so common among her sex. Perhaps as common a form of headache is that known as migraine. It is supposed to have its origin in a tendency of certain tissues of the brain near the pons to take on by exciting causes slight inflammation, or severe congestion. These headaches generally come on after various gastric disturbances, the use of strong tea, or alcoholic drinks, overloading the stomach with indigestible food, especially hot biscuits or hot bread, over-fatigue, night work, nervous excitement, worry, etc. These, however, are only the exciting causes, the predisposing causes being the tendency of these tissues to take on a highly congested state, as before stated. If the sufferer will carefully avoid these habits which bring on the disease the attacks will be less frequent and less severe. In very many cases it may be cut short altogether or greatly mitigated in its severity by proper treatment. A hot foot and a leg bath continued for 30 minutes, while the head is manipulated by the band of an attendant frequently dipped in cold water, will often alleviate or cure an attack. What is known as magnetizing the head will often cure the worst cases and send them to sleep. Both these methods are very simple and effective. Shampooing the head, as is done by a barber, is sometimes effective. To this ladies often object, as they do not like to wet their long hair. An instrument has been invented by which a lady's hair may be thoroughly shampooed without disturbing the clothing, and dried in a few minutes by steam; and if it could come into general use in cities it would be a boon to women.

Persons who are subject to headaches should wear as little hair as they can, and if they would wear it short, and thoroughly wet and rub their heads every day it would be very beneficial. Hot water applied to the back of the head and spine will often stimulate the vaso-motor nerves to contract the vessels of the brain and discharge their contents, thus relieving the congestion. A stream of hot water from a fine spray along the spine will do the same.

As a rule, however, the latter means are inaccessible to most persons, and so the former will be more appropriate. It is very desirable to break up the habit so far as possible, so as to make it unnecessary to cure; and this is done by whatever permanently invigorates the system and equalizes the circulation. Bathing and friction to the skin, and a simple, healthful diet are of this first importance. Out-of-door exercise is equally necessary.

Hot and Cold Baths.

The *London Lancet*, in a recent number, points out the difference between the effects of hot and cold baths. The effects of the cold bath, it says, being mainly due to impressions made upon the cutaneous nerves, the modifications of the cold bath largely depend on their power of increasing its stimulating action. The colder the water, the more violent the impression. The frequent change of water, such as is found in the sea or in running streams, increases the stimulating effect. Great force of impact, as when water falls from a height or comes forcibly through a hose upon the body; the division of the stream, as is seen in shower baths and needles baths, and the addition of acids or salt to the water, all act, it would seem, by increasing the stimulating power which the water exerts upon the cutaneous nerves. Warm baths produce an effect upon the skin directly contrary to that brought about by cold water. The cutaneous vessels dilate immediately under the influence of heat, and although this dilation is followed by a contraction of the vessels, this contraction is seldom excessive; and the ultimate result of a warm bath is to increase the cutaneous circulation. The pulse and respiration are both quickened as in the cold bath. The warm bath increases the temperature of the body, and, by lessening the necessity for the internal production of heat, increases the call made upon certain vital processes, and enables life to be maintained with a less expenditure of force. While a cold bath causes a certain stiffness of the muscles, if continued for too long a time, a warm bath relieves stiffness and fatigue. The ultimate results of hot and cold baths, if their temperature be moderate, are about the same, the difference being, to use the words of Braun, that "cold refreshes by stimulating the functions, heat by physically facilitating them; and in this lies the important practical difference between the cold-water and hot-water systems."

DANDRUFF CURED.—The belief that dandruff arises from a disease of the skin, although physicians don't seem to agree on this point, and the knowledge that the use of sulphur is frequently attended with very happy results in such diseases, induced me to try it in my own case. A preparation of one ounce flowers of sulphur and one quart of water was made. The clear liquid was poured off, after the mixture had been repeatedly agitated during the intervals of a few hours, and the head saturated with this every morning. In a few weeks every trace of dandruff had disappeared, the hair became soft and glossy, and now, after a discontinuance of the treatment for eighteen months, there is no indication of a return of the disease. I do not pretend to explain the *modus operandi* of the treatment, for it is well known that sublimed sulphur is almost or wholly insoluble, and the liquid used was destitute of taste, color or smell. The effects speak for itself. Other persons to whom it has been recommended have had the same results, and I communicate the result of my experiments in the belief that it may be valuable and acceptable to many who have suffered in the same manner as myself.—*American Journal of Pharmacy*.

THE WAY TO HEALTH.—The only true way to health is that which common sense dictates to men. Live within the bounds of reason. Eat moderately, drink temperately, sleep regularly, avoid excess in anything, and preserve a conscience "void of offense." Some men eat themselves to death, some drink themselves to death, some wear out their lives by indolences, and some by over-exertion, others are killed by doctors, while not a few sink into the grave under the effects of vicious and beastly practices. All the medicines in creation are not worth a farthing to a man who is constantly and habitually violating the laws of his own nature. All the medical science in the world cannot save him from a premature grave. With a suicidal course of conduct, he is planting the seeds of decay in his own constitution, and accelerating the destruction of his own life.

COOLING THE HEAD.—Bay rum has a great reputation for this, and no doubt deserves it; but we believe that cold water is as good a remedy for the head as any, whether in the form of a shower bath or applied by a towel. In some forms of disease, so strong a cooling remedy as ice is beneficial; but this should never be applied except under the direction of a physician who watches the patient, because if applied when not needed, or if applied too long, it may act very injuriously.

A NEW mode of treating cancerous growths, tumors, etc., is to subject them to a stream of hot, dry air. This is proposed and has been successfully applied by Dr. G. A. Keyworth, of England.

TABLE OF CONTENTS.

EDITORIALS.—Superiority of Prehistoric American Wares; Combined Steam Pump and Engine; Salmon River Improvements; Pulverizer and Amalgamator, 337. The Week; A Reward to Inventors; Mining Law Suggestions; Trademark Law Unconstitutional, 340. New Mexican Copper Mines; Melting Copper Ore in the Mine; A New Harness Snap; Special Mining News; Columbia School of Mines; Cleopatra's Needle; The Deepest Mine on the Continent; The American Lubricator, 345. Notices of Recent Patents; Decisions in Patent Cases, etc., 348.

ILLUSTRATIONS.—Cope & Maxwell's Combined Steam Pump and Engine, 337. The Covert Harness Snap; The American Lubricator, 345.

CORRESPONDENCE.—The Debris Question, or Cleaning the Rivers for the Gold; Como, Nevada, 338.

USEFUL INFORMATION.—A New Fluorescent Body; How Bog Oak Ornaments are Made; How to Determine the Quality of Silk; To Convert Agates into Onyx; To Prevent Nets from Rotting; Fruitfulness of a Grain of Wheat; Dry Packing for Marine Engine, etc.; Light Buffer Springs; To Prevent Leaks, 343.

GOOD HEALTH.—Headache; Hot and Cold Baths; Dandruff Cured; The Way to Health; Cooling the Head, 343.

MECHANICAL PROGRESS.—Friedman's Ejector; Heat of Carbons in Electric Light; The Swiftest Ship in the World; The Electric Hose; Patent Fastener for Machinery; An Electric Sentinel; Application of Electrical Power to Agriculture; Nickel Bronze, 339.

SCIENTIFIC PROGRESS.—Iron and Steel in the Arts; Optical Telegraphy; The Influence of Silicon on Steel; New Species of Fish; A Mammoth; Origin of Petroleum, 339.

MINING STOCK MARKET.—Sales of the San Francisco, California and Pacific Stock Boards. Notices of Assessments, Meeting and Dividends, 340.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico and Oregon, 341-343.

MISCELLANEOUS.—The Deepest Well in the World; Sonora, Mexico, 338. A Strange Arctic Region; Shipping Laws of the United States; Mining Decisions; The Boom in the Lumber Interest; Relics of the Mound Builders; A Practical Calculating Machine; The Microscope in the Witness Box, 342. Influence of Planetary Movements; A Large Electro-Magnet, 343.

The Week.

One of the events of the week is the occurrence of Thanksgiving day, the observance of which is specified in the President's and reiterated in the Governor's proclamation, a day of general rejoicing to all except to the unfortunate turkeys, which are compelled to participate in the observance of the day. On this coast we do not feel the dread blasts of winter, nor witness the snowy-covered fields, which form a marked contrast with the appearance of the day in the Eastern States.

Severe weather has in some places delayed mining operations, but very little damage has been done. General preparations are going on for renewed activity in mining, in spite of the setback of a few stormy days.

The rains give promise of a good water supply, and there is no occasion for fears of the future in that respect. Most of our exchanges concur in saying that there is more activity in mines just now than at any time within the previous ten years. Many new discoveries are reported from the old mountain mining counties, and the general outlook is good. There seems to be some apprehension on the part of the farming community that the miners, having gained the day in the Supreme Court, will now proceed to ruin the agricultural element; but we are assured by our mining exchanges that nothing but justice will be exacted, and the golden rule carried out. The wholesale attempt to crush mining enterprise at one sweep must cause some hard feelings, yet we are sure the farmers will understand the miners better, whether that knowledge is gained through sad experience or otherwise. Every indication points to the propriety of good feeling and a general renewal of prosperity, instead of the damaging and fatal personal warfare that may be kept up whenever the courts are invoked to settle questions, which brotherly love and true business instincts are abundantly competent to arrange amicably.

A Reward to Inventors.

At a recent meeting at Chicago of the American Humans Association, a prize of \$5,000 was offered for an improved stock car capable of carrying live animals long distances without needless suffering.

We certainly think that the inventor who will contrive a cattle car free from objectionable features, will reap a reward compared with which the offer of \$5,000 would be a small sum. There is undoubtedly room for invention in this business, and the demand for an alleviation of the sufferings of cattle during transportation is becoming greater, as the carrying of stock on railroads increases in magnitude. It has been estimated that the saving in shrinkage in cattle between Kansas City and New York or Philadelphia, by proper appliances for food and water while en route, would nearly pay the cost of transportation, hence the opportunity to inventors to reap an immense reward.

There are numerous patents upon cattle cars, and many efforts have been made to introduce them, but the general similarity of design occasioned suits for infringement, which virtually destroyed their humane utility.

The old National Cattle Car Co., of Chicago, with Zadoc Street and his son John W. Street, procured the manufacture of about thirty cattle cars, by the McNairy & Cladin Manufacturing Co., of Cleveland, Ohio. The cars contained all of the appliances peculiar to cattle cars, viz.: feed boxes and water troughs, by which the animals could be cared for from the outside of the car, and flexible slatbars, forming the stalls. Some of them were even padded. Several carloads of cattle were transported successfully in them from St. Louis to Philadelphia. But, unfortunately, it was claimed that the company were infringing upon patents owned by Amos Bank, of Salem, Ohio, and John W. Gill, of Columbus, Ohio, which gentlemen had made preparations, with a capital of \$100,000, to build these same, or substantially the same kind of cars. The matter got into the courts and terminated the usefulness of the inventions, because railroad companies preferred a clear title to the patented contrivances used upon their lines, and hence would have none of them. We give this slight sketch because Mr. Zadoc Street seems to be an active member of the American Humane Association. He owns a number of patents and would undoubtedly be glad to have them put into use upon the railroads. The matter is one which would bring enormous advantages to an inventor, and we urge upon all those interested to strain a point and examine the question, although the matter of the reward of \$5,000 is a very small inducement, as the properly constructed cattle car would have the transportation of the millions of live stock annually carried from the plains of the West to the Atlantic seaboard.

The main points to be observed in a cattle car are to provide moveable stalls for each animal, allowing them freedom of action in standing or lying, and to prevent them from interfering with each other. The slats or bars composing the stalls frequently gall or skin the animals, which strike against them when the train stops or moves ahead, and this must be provided against. Means of feeding and watering from the outside must be provided, and above all, provision should be made to counteract the jarring motion of the car, which seems to have a bad effect upon the animals. This latter point has never been touched in former patents, and was suggested as a proper subject of inquiry by a high judicial officer some years ago. In the case of hogs and sheep, small pens should be provided so that danger from smothering will be avoided. The great object of the inventor in this line must be to provide a means of transporting cattle so as to reduce their shrinkage to a minimum.

SIERRA MOJADA MINES.—Two miners of San Antonio, Texas, returned home after two months prospecting in these mines, and report plenty of rich ores, but nothing fabulous. They say that the ore will assay from \$90 to \$180 per ton. Over one hundred mines have been located. Another prospector writes to a Tucson paper and discounts largely the reported fabulous richness of the new discovery. The writer speaks disparagingly of the new district. On the other hand, Prof. Schnchart, engineer appointed by the State of Coahuila, a man of great experience, freely gives his opinion as to the paying quality of the Sierra Mojada mines: he finds lumps of silver lying around loose. Capital, science and labor are necessary; 1,200 are now at the mines, 70 of whom are Americans. Plenty of drinking water, wood and provisions are abundant at moderate prices, good grazing, machinery greatly wanted. Ore is found on the surface assays of which will pay a handsome profit to a stamp mill. The location of these mines, so far as our information goes, is as follows: 450 miles south of El Paso, 250 miles northeast of Mazatlan, 400 miles due west from Corpus Christi and 350 miles southwest of the present terminus of a railroad in southwestern Texas which connects directly with Galveston, New Orleans, Shreveport and St. Louis.

By the burning of the British steamer *Bremer Castle*, at Singapore, the New York underwriters will lose from half to three-quarters of a million of dollars.

Mining Law Suggestions.

In his testimony before the Land Commission, ex-Senator Sargent furnishes some very interesting information upon the workings of our present mining laws. Mr. Sargent considers the laws relating to placer claims excellent.

In regard to the title, particularly to ancient claims, the statute dispenses with proof of original location and the chain of title reaching beyond the period of the statute of limitations, makes it possible to acquire the right to these claims with certainty. Some rule might be prescribed which would govern original locations to be hereafter made, but it would be difficult to prescribe one that would operate equally in reference to development and working. So much depends in placer mining upon water, and the seasons are so uncertain and water is so frequently scarce, that, unlike the case of quartz mining, regular or profitable work, work in good faith, and not mere form or show of work, is often impossible for considerable periods of time. A claim may depend wholly on the rains for water, and get none during a dry season. If the law should require so much work on a mine every year during that dry year it could not be obeyed, at least, in good faith.

There seems to be no objection to the consolidation of two or more claims in the hands of one person or company by purchase. Indeed, this is often necessary for purposes of development. An individual or company may be willing to undertake the construction of a head-race tunnel or long water ditch for the mineral presumably in two or three claims, but not for that in one. The law should not hinder such enterprises.

While the laws relating to placer claims, would need but slight changes, the laws for the location and purchase of lode claims are in a much more unsatisfactory condition.

Where the "croppings" of a ledge are not visible through the whole length of a claim, the miner may expend thousands, perhaps a hundred thousand dollars, in determining the course of the vein, only to find that his location embraces but a small part of it, and some one who has not spent a dollar may get the lode by an adjoining location.

Under the recent ruling of the Supreme Court of the United States, when a ledge goes out of the surface lines of a claimant he has no right to follow it. This is, perhaps, a fair interpretation of the quartz laws, but it suggests the need of amendment to avoid a great hardship and injustice to discoverers. The old miners' law treated the subject better, and gave a locator so many feet from his starting point in any direction "following the ledge, with all its spurs, dips, angles and variations." This is common sense, and it secured to the discoverer or developer of a ledge the full extent of his claim, no matter in what direction it ran underground. It is often impossible to determine where the "apex" of a vein is, or its course, or the angle or direction of the dip, by the early workings, and, therefore, the intended rights of a discoverer are poorly defined and protected in locating a claim under existing laws. The impossibility of determining these things without extensive development, which must follow and not precede location, has led to much litigation and injustice.

Another feature of mining locations that leads to litigation, is where the discoverers of veins, or their assigns, are compelled to defend their rights from subsequent locators in their immediate neighborhood when the legal attack is directed to the portion of the dip of the lode which has passed beyond the exterior lines of the surface tract. But a quartz mine would be of no value, in most cases, where the locator had not the legal right to follow his ledge down at any angle it might take, and to any distance. Only claims of extraordinary richness could be worked where the possessors were confined within perpendicular side lines.

It is essential to retain in the United States mineral laws a provision by which locators can follow the dip of their claims outside their side lines, even if litigation does sometimes ensue. Such litigation is caused by questions as to identity of ledges and not from abstruse questions of principle. The Government, in dealing with these matters, must get nearer to, rather than farther from, the old mining laws, which gave the locator his ledge wherever it dipped or however it crooked. It was still a question of identity, often contested, but the laws did as much as possible towards assuring a workable claim to the discoverer and his associates.

The only safe rule is to let the miner follow his ledge wherever it goes in direction or dip, without regard to surface ground. If that right is restricted, mining is rendered hazardous and uncertain to the extent it is restricted.

The Nicaraguan Minister says he will meet Grant in Philadelphia early in December. Ammen has assurances that if \$20,000,000 of stock can be sold in the United States, the balance of the \$100,000,000 can be obtained in France without going to England for the money. French capitalists desire the control to be kept in that nation.

M. PALEN, of San Bernardino, is mining for coal in the mountains some ten miles from that place. We saw favorable looking croppings from the ledge exhibited at Starke's hotel.

Trade-Mark Law Unconstitutional.

The Supreme Court of the United States on the 17th of November inst. adjudged the act of July 8th, 1870, regulating the registration of trade-marks to be unconstitutional. It appears that under this law about 8,000 trade-marks have been registered, and about 200 applications for registry are now pending. Prior to the passage of this above act, there was a general desire to devise some means of providing for the recording of brands, or trade-marks, used by business men to identify their goods. The common law gave them the right to proceed in damages against any person who should counterfeit the same, and this right was not intended to be taken away by the act of Congress. The difficulty in the way of successfully prosecuting a suit for damages lay mainly in the proof of novelty of design. This was accomplished by showing priority as to time, which could not always be done by reason of exact dates, not having been entered of record. Hence, many persons presented their trade-marks for record to the clerks of the United States District Courts under the copyright laws, which afforded no protection; indeed it was declared by the courts that trade-marks could not be the subject of copyright. And orders were issued the clerks of the United States District to refuse certificates of copyright to all persons applying for the same upon trade-marks, this distinction being that the copyright laws were intended to apply, among other things, to such objects as could be denominated works of arts, possessing an intrinsic value and intended for sale as such. The trade-mark possessed none of these requirements, being only a badge, or label, intended to be attached or affixed to some other object of value. Besides trade-marks were amply protected by common law, and not a few lower courts had decided that where a party availed himself of the benefits of an act of Congress he had at least constructively abandoned his common law rights, and hence could not recover damages in the State courts, but must proceed in the United States courts under the act. Now when proceedings were commenced in the United States courts for damages for the infringement of a registered trade-mark, it was urged upon these courts that there was no remedy because the common law afforded ample protection, and the act of Congress had no *raison d'être*. This reasoning, however, in either case could only be applied to those who had taken advantage of the act of Congress and registered their marks. Where parties relied upon their common law rights, the objections could not prevail. Now it appears that the act itself has been declared unconstitutional.

It was urged upon the Supreme Court, in defence of the legislation relating to trade-marks, that Congress has power to pass laws "to promote the progress of science and the useful arts by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." The court decided that a trade-mark has no necessary connection with inventions or discoveries. It was also argued that the Constitution provides that Congress shall have power "to regulate commerce with foreign nations and among the several States and with the Indian tribes." The court declared that the legislation in question does not limit the use of trade-marks to inter-State or international commerce, as it should do if based upon the constitutional provision cited; nor does that clause of the Constitution bring within the control of Congress every species of property used in commerce.

While denying the constitutionality of legislation by Congress for the regulation of trade-marks, the court desired to leave untouched the question of the right of Congress to regulate the use of trade-marks by treaties with other nations. The United States have such treaties with several nations, and others may be made from time to time. No opinion as to the right of the Government to enter into such treaties has yet been given. It is simply affirmed that Congress has no power to pass laws for the protection of the rights of persons to the use of any particular trade-mark. The decision is important, and therefore it should be thoroughly understood.

The Secretary of the Interior, in consequence of pending applications, has issued instructions suspending action on pending applications until the desire of the applicants to proceed has been manifested; and further that "trade-marks will hereafter be registered on pending or future applications only in favor of those persons who, with full knowledge of the decision of the Supreme Court, shall request such registration. The fees heretofore paid in trade-mark cases cannot be refunded without further legislation by Congress."

The agricultural lands of the Northern Pacific railroad west of the Missouri river, to Puget sound, are to be offered for sale to actual settlers at the Government prices, \$2.50 cash per acre, with an addition thereto of 10 cents per acre to be paid to the company to reimburse it for the cost of selecting, surveying and conveying such land.

RICHARD K. EVANS, Esq., was married to Miss Fannie Virginia Brown, in Washington City, Nov. 20th.

New Mexican Copper Mines.

Considerable apprehension is manifested by those interested in copper mining, that the development of the rich copper mines of New Mexico will practically exclude the other mines in the United States, if not most of those in the world.

One of the richest deposits is at Clifton, 93 miles almost due west from Silver City, and between 60 and 75 miles from Ralston, now possibly better known as Coronada. The ore seems almost unlimited in quantity—in fact there is a solid mountain of copper. To prove this, the first development was by tunnel at the base, and from which drifts were carried in all directions, shafts in the meantime being sunk from above the ores from the top showing fully as rich as those at the bottom.

The smelting works and attendance building are in a canyon on the Fresno river, near where it empties into the Gila. Fuel has to be brought 35 miles and costs \$40 a ton, 15 tons being required to smelt a ton of copper. Cartage to the nearest railway station at Otero costs \$70 a ton, yet business is carried on at a large profit.

At Santa Rita, near Silver City, are extensive copper deposits, which have been worked for over 100 years. While yet Mexican territory these mines were worked mainly by convict labor, and at times by hired natives. The deposits are of various kinds of copper ore and native copper in the seams of the rocks. It was for the latter that mining was carried on in former years. There is an abundance of rich ores over a large district, but at present the mines are in the hands of speculators and not being worked. The extreme difficulty of getting transportation for the metal to the end of the railroad has also, no doubt, had an important bearing upon the cessation of labor upon the mines. The ores of the Santa Rita and Hancock districts adjoining are in the form of immense deposits, and, while rich, are unlimited in quantity. Further west the Burro mountains contain large deposits of copper, and still further, at Coronada, are several mines of great magnitude, of low grade ores, which cannot be worked at present for want of fuel and water. Up the valley of the Rio Grande and 18 miles east of Bernalillo, which is hardly more than 250 miles from the Colorado boundary, is the great copper district of the Puerto Westward, and beyond the territorial line into Arizona are copper deposits of much magnitude.

Melting Copper Ores in the Mine.

C. M. Tessie du Motay, the noted Parisian chemist, who has paid considerable attention to metallurgical processes, and E. Stern, of New York, have devised a somewhat curious process and apparatus for melting ores in their natural situation. Their proposition is a startling one, which practical miners will hardly believe practicable. It consists in directing against ores in their natural situation in the mine, an intensely hot flame, preferably that produced by what is known as the compound blow-pipe. The apparatus consists in the arrangement of blow-pipes for carrying out the process, namely, a series or crown of blow-pipes surrounding a central pipe, all of said pipes being arranged upon a carriage so as to be readily brought into contact with the ores in their natural situation.

This process is supposed to be particularly useful in the reworking of those masses of native copper which are too tough to be cut up by knives or blasted with powder with any economy. It is claimed by the inventors, however, to be used on other similar ores, thus avoiding the necessity of cutting or breaking them up. In this class they include native copper, sulphurets of iron and copper, higher sulphurets of iron, copper and lead, antimonial ores, etc.

This blow-pipe is composed of several crowns or series of piping supplied with a mixture of gas and air blown in the direction of the center of fusion. It is traversed by one or more air, gas and coal-dust pipes, thus concentrating the whole of the caloric power of the fire upon the zone to be melted and preventing the caloric from being dispersed, owing to its being stored in the rock to be melted.

In consequence of the injection of coal-dust in the direction of the center of fusion, no oxidation can take place, either of the metals or of the sulphureted compounds to be extracted by fire. The coal-dust may be substituted by tar, petroleum or other hydrocarbons.

A New Harness Snap.

The cut shown herewith represents the Covert harness snap, made by the Covert Manufacturing Co., of Troy, New York. It is intended as a snap for use on any part of harness where necessary. The hook is opened by drawing back the button, and on releasing it, the spring pushes the slide back up into the end of the hook so as to close it.

DISTURBANCES occurred among the students of the St. Petersburg University, resulting in several arrests and in the closing of the library by order of the Governor-General. Statements in regard to the origin of disturbances are conflicting.

Special Mining News.

The *Herald*, published at Bonanza City, Idaho, proposes to publish a special mining edition. The editor says: "We have visited personally and made notes thereon, and the new districts that we have been unable to visit have been noted carefully by prospectors and miners acquainted with the discoveries and developments. The necessary material is now in hand, with the exception of Bay Horse, Poverty Flat, Kinnickinick and Rams-horn mines, at the southeast end of the belt, and a report from these is being made up by Judge Onderdonk and Maurice McGrath (Winnemuck) and will reach us by Monday's mail."

"The edition will be soon published, and will include the prominent mines in the Wood River, Salmon River, Yankee Fork and other mineral regions. The object of this special edition is the dissemination of knowledge regarding the mineral resources of central Idaho. The *Herald*, in common with many others, receives numerous letters from parties at a distance seeking information about our mines. To answer all these inquiries is next to impossible. Hence we have adopted this plan and will print a large extra edition of the *Herald* to send abroad. It will make a showing equal to, if not exceeding, that of any other new mineral field on the continent."

With reference to this subject, we notice that a few of our exchanges are beginning to publish a complete monthly mining summary. If all papers published in our mining counties were to devote space to a complete resume of the mining interests of their respective counties, say once a month or once every two weeks, this together with daily items, would constitute a fund of information which would soon place our mining business before the world on a certain and substantial basis.

We make this suggestion to all of our exchanges, with no other object in view than to concentrate the record of our mining progress in an orderly manner. Let every miner have a hearing, every prospector a notice of his doings. To bring about a brisk revival of mining operations we must make our mines known, and specify where they may be found. Tremendous inducements in the shape of information and in regard to mineral resources are being held out to the world by adjoining States and Territories, and unless California wakes up to the fact that money exists in enormous quantities in the East and in Europe, awaiting investment in mines, other regions will secure it, or else, by their exaggerated accounts, cause capital to be diverted into other and less solid investments.

The Covert Harness Snap.

It is gold that the world wants, and there never will be a glut. We have enough gold in this State to satisfy the market as much as it ever can be, but the idea of where and how it is to be worked out of our soil is so indefinite, comparatively, that nothing but full and accurate information can bring about the working of our deposits on a grand scale. It is the desire to procure this information that has prompted us to make these remarks.

A NEW PROPELLER.—A new form of propeller recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by John B. Ward of this city, was tried last week on Lake Chabot, back of San Leandro. The little boat on which it was tried was built here, but the engines, boilers, etc., are of Eastern make, having been purchased at the Centennial exhibition, and presented to Mr. Chabot. The boat runs well with her present propeller, but a decided improvement in speed was made by that of Mr. Ward's invention. Over a measured distance, with 105 pounds of steam, with no wind, she made the distance in six and a half minutes. She was then hauled out and a propeller of the same diameter substituted for her own. With the new propeller she made the distance in five and a half minutes, with 70 pounds of steam and a head wind. Again the propeller was changed, this time another of the improved form, same diameter, but removable blades slightly thicker. The same distance was made in five minutes with eighty-five pounds of steam; throttle half open and forward door open. The last trial showed that a greater speed was attained with a very much lessened consumption of steam. The new propeller does not differ materially from that commonly in use, but it is constructed upon peculiar mathematical principles, so as to give the best effect. The edge resistance is much lessened, and it makes no bubbles or foam, cutting the water cleanly, and utilizing its whole power in propelling the boat ahead. Further experiments are to be tried on a larger scale, but those referred to proved the efficiency of the device to those who were present at the trial.

HORSE THIEVES are infesting Ventura county.

Columbia School of Mines.

This college established in New York City, and growing in importance as a national institution, has just issued the first number of volume one of a quarterly entitled "The School of Mines Quarterly." It is published under the auspices of the Chemical and Engineering Societies of the School of Mines, and is issued in November, January, March and May, Fortyninth street (cor. 4th avenue), New York City, N. Y. The subscription price per year, including postage is one dollar, which price places it within the means of a numerous clientele. If the editorial staff and the contents of the first number are any criterion, there need not be any fear as to the success of the publication. We are glad to place such serials upon our exchange list, since they form a medium of communication between our growing institutions and the world at large. In times not very recent the proceedings of our societies and educational establishments were confined to the few, but the fact that nearly all are availing themselves of the printing press for the universal dissemination of knowledge, indicates a desire on the part of the public to acquire information and a consequent revival of intellectual development, as well as a disposition on the part of our colleges and scientific societies to foster that desire.

The table of contents, showing excellent original matter, is as follows: The Pedometer as a Surveying Instrument, by Prof. H. S. Munroe; Coffee and its Adulterations, by F. Weichmann; Fire Brick and Terra Cotta, by A. McL. Parker; Chloral, by A. P. Hallock; Building Stones, I, by J. L. Greenleaf; Editorial; Notes on Mineralogy and Physics, by C. A. Colton, E. M., and M. C. Ihlsing, Ph. D. We have no criticism to make for the reason that no foundation for criticism occurs to us. The sensation of "newness" and the

The American Lubricator.

fear of adverse criticism will always, in our judgment, have a tendency to increase the merits of this new and welcome quarterly, by inducing constant care and variety in the interesting and instructive matter to which its pages are intended to be devoted.

WATER-RIGHT DECISION.—The Supreme Court of the United States has affirmed the judgment of the Supreme Court of California in the case of Oswald Broder vs. The Natoma Water and Mining Company. The most important question presented by the case is, whether a person who has constructed a canal or ditch for the purposes of mining or irrigation, upon the public lands of the United States, can be forced to abandon the same by another person claiming title to the lands under a subsequent Government grant made to one of the Pacific railroads. In 1866 Congress passed an act for the protection of the owners of ditches and canals constructed on the lands of the United States, and for the establishment of their rights as against subsequent grantees of the Government; but the complainant in the present case acquired title before that law was enacted, and maintains that the law should not be made retroactive in order to defeat his claims. The Court holds that the rights of owners of ditches and canals, in such cases, are rights which the Government, by its conduct, had recognized and encouraged, and was bound to protect, even before the passage of the act of 1866; and that that act was rather a voluntary recognition of a pre-existing right, constituting a valid claim to its continued use, than the establishment of a new right. It makes no difference, therefore, whether the complainant acquired title to the land in question through a Government grant to the Central Pacific Railroad Company, before or after the passage of the act of 1866. In either case, he took it subject to the right of way of the owners of the canal, tacitly or formally recognized by the Government, and that right cannot now be disturbed.

IN consequence of recent developments, the directors of one Bremen steamship company have decided to refuse transportation of their vessels to the class of heavy French silks which are so weighty with chemicals and oils as to cause danger of spontaneous combustion.

Cleopatra's Needle.

The recent difficulties concerning the obelisk which the Khedive of Egypt presented to Americans, had its origin in the natural dislike of the Egyptians to the dismantling of their country of works of art. The *Young Egypt*, published at Alexandria, in Arabic and French, expresses its sentiments in the following manner:

"America is making preparations to take away from us the sole obelisk of Cleopatra which we now possess. This news astonishes us, and we cannot believe that it is true. This monument belongs to the country, and no one can dispose of it without the authorization of the nation. If this be allowed, we may find some day that the pyramids are transformed into stone quarries and used for building houses. The time has come when more attention should be given to the preservation of our artistic wealth, and more respect accorded to the vestiges of the past, which once made Egypt glorious."

The *New York Star* some time ago published a long account of the artificial manufacture of this obelisk by an American, who was employed for the purpose by the Khedive, at the time of the donation of a similar one to England. It was alleged that the religious superstitions of the people would not permit the removal of the original, and so it was resolved to boot-wink them into the belief that an imitation obelisk would be palmed off on the English. While to the British the Khedive explained that the original would be sent to England and the imitation kept to satisfy the religious prejudices of the priests. So this American sculptor made an exact counterpart of the original, done in cement after the manner of a Portland cement pavement. Of course there is nothing fabulous in the star story. In any event it will not make much difference to New York whether the obelisk is original or a base imitation, provided it came from Egypt, it will do. We sympathize with the Egyptians in their efforts to stop the removal of their works of art. The removal of a pyramid is well suggested by *Young Egypt*. We bespeak one for the Pacific coast.

The Deepest Mine on the Continent.

On the 23d of November, says the *Gold Hill News*, the incline of the Belcher mine, on the Comstock, reached a perpendicular depth of 3,000 feet, and is 300 feet deeper than any other mine on the lode and the deepest mine on the continent. The incline starts from the 900 level and makes its plunge at such an angle as to require the incline to run about 160 feet to make 100 feet perpendicular depth; and hence stretches away about 3,360 feet. In making this depth of 2,100 feet perpendicularly, the incline carries the workings in the bottom 2,625 feet to the east of the shaft. Any one curious to know where the line of the shaft is, can therefore measure off east of the air shaft 15 feet less than a half mile. It must be somewhere east of a portion of the Twin Peaks mine and, in fact, over the hills and a great way off. They have big reels at the mine which are capable of carrying 7,000 feet of cable, but this rope in use at present is really 80 feet less than a mile long.

The Belcher is now sinking a sump, preparatory to opening the 3000 level and exploring the ore vein at that depth. The mine is in the best of order, and well ventilated, and should ore be found on the 3000 level no delays will be necessary in order to commence stopping it out. In a few days she will have pumps down that depth and in running order. Her engine can run a double column of them to that depth if necessary. It is an upright, compound condenser, with initial cylinder 30x126 inches, and expansion cylinder 62x96 inches—dimensions which are only exceeded at the Forman and the Chollar-Norcross-Savage shaft, and by the new engine being placed at the Union shaft.

The American Lubricator.

This improved lubricator, for which Tatum & Bowen, No. 3 Fremont street, are agents, has only recently been introduced on this coast, although there are upwards of 7,000 in use elsewhere. It feeds the oil into the steam pipe of the engine at a point above the throttle valve, thus infusing the steam with foam of oil, and as the lubricated steam passes through the throttle, governor, steam chest and cylinder it lubricates all those parts. Every drop of oil is visible as it passes into the steam pipe.

The lubricator, working in this way, imparts a regular motion to the engine, because it lubricates the governor valve, and the throttle is easy to turn at any time, it being kept from rusting and cutting. The friction of the valve is relieved, and the packing around the stems is oiled. The American Lubricator is made with special machinery and is interchangeable, so that any part can be duplicated by mail.

The Governor has commissioned Thomas W. Younger as First Lieutenant, and T. W. Stevens as Second Lieutenant, of the City Guard of Sacramento. Also E. E. White, Notary, Tuolumne county; W. H. Grant, Notary, Yolo county; and A. J. Kasten, Notary, Solano county.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and potassium dichromate, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the construction and operation of a stamp, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tellings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a valuable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., Mining and Scientific Press, 202 Sansome Street, San Francisco.

ARITHMETIC MADE EASY BY ROPP'S EASY CALCULATOR.

This valuable work is used by thousands of farmers, mechanics and business men, and is highly recommended for its practical utility and convenience. It embodies an entirely new system of calculation, by which a vast amount of figures and mental labor—required by the ordinary methods—and fractions with their complexities, are absolutely avoided.

It is so simple and easily comprehended that even the most illiterate is enabled, in a few minutes, to reckon with absolute accuracy and speed; while its original and rapid methods, benefit and delight the most scholarly. It shows at a glance the accurate value of wheat, corn, rye, oats, barley, cattle, hogs, hay, coal, lumber and merchandise, from one pound to a car load, and for any price the market is likely to reach.

It gives the interest, simple and compound, on any sum, or any time, at six, seven, eight, and ten per cent.; the exact measurement of boards, scantlings, timbers, saw logs, cisterns, tanks, wells, granaries, bins, wagon beds, corn cribs, etc., the wages at various rates, for hours, days, weeks and months; besides numerous other important methods, rules and tables.

It is printed on fine tinted paper, is well and elegantly bound in pocket-book shape, and accompanied by a silicate slate, pocket for papers, and memorandum, which can be replenished in the two latter styles.

It answers the purpose of a pocket book and diary, and costs no more, although it was gotten up at great expense and labor, and is unquestionably one of the most useful publications ever issued from the press.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter or receipted by express. Address

Grimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. 8vo. Illustrated. By ROBERT GRIMSHAW.

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the saw scientifically, analyzing its action and describing, under the leading classes of Resawing, Cutting and Continuous Acting Saws, the various kinds of large and small Hand, Sash, Muley, Jay, Drag, Circular, Cylinder and Band Saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, iron, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, sawing, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, \$1.50. Orders for first edition received now.

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., 202 Sansome St., S. F.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of PHOSPHATE SOAP, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use PHOSPHATE SOAP.

For happy hands the constant use of PHOSPHATE SOAP will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879.

To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your PHOSPHATE SOAP as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.

SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:

I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, Pruritus, the other an Eczema. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.,
128 O'Farrell St.

To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:

I have tried your PHOSPHATE SOAP, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. HENRY H. LYNCH,
515 Haight street.

The genuine merits of PHOSPHATE SOAP and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Ad-
justed than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hol-
ing coal or building material, etc. It will do the work of a
Steam Engine with one-tenth the expense. One Horse can
easily hold over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be
affected by exposure. The hoisting-drum is thrown out of
gear by the lever, while the load is held in place with a brake
by the man tending bucket. The frame of the Power is
bolted to bed-timbers, thus avoiding all frame work. When
required these Powers are made in sections for packing.

Mines and Works of Almaden.

Translated from "Annales des Mines"

By F. B. CHRISTY.

Full geological description of this famous Quicksilver
Mine, illustrated by maps and plans of the works. Com-
plete description of the Quicksilver Furnaces and Con-
densers, etc. 48 pages octavo—paper cover—price (post-
paid) 50 Cts. Published and sold by DEWEY & CO., 202
Sansome Street, S. F.

CONTINUED FROM PAGE 341.

and prospects appear favorable. The witze on the 10th level looks first rate; in the drift we have low-grade ore that will pay well when we get the place opened up in shape. We are making all due preparations to start work on the black ledge, so as to have a good quantity of ore on hand when the furnace starts up. Mr. Kibbourne was in town last night and reports the grading for the furnace finished and is getting ready for the stone work. The mill is running smoothly and everything around the mine likewise.

SANTA FE DISTRICT.

RICH DISCOVERY.—The Esmeralda Herald speaks of a very rich discovery about five miles in a northerly direction from the famous Sunrise mine. The ore is a black sulphuret, galena and antimony. The rock was taken from the surface, and several assays were made, ranging from \$2,200 to \$2,020. The vein is 22 inches wide, and in a limestone formation. It is pronounced by old prospectors to be the greatest discovery ever known. Work will be commenced on it immediately.

ARIZONA.

SILVER PRINCE.—Arizona: Mr. Curtin, who, with Hotaling, is owner in the Prince, informs us that there is now on the dump, at the mine, 100 tons of ore that will mill \$400 to the ton throughout, which is a pretty good showing for any mine. But the best is not told. Three men recently took from the mine, in one day, five tons of ore worth \$1,000 per ton, and there is four of this ore in the ledge now in sight.

COLORADO.

CLARK CREEK COUNTY.—Miner: The Magnet and Sequel mines are associated properties on Saxon mountain, and are under the superintendency of E. Le Neve Foster. They have lately been worked by Hopkins, Whitrow & Co., and are turning out profitable quantities of ore. In the lower drift there are 10 inches of nearly solid ore, in the bottom, and two streaks in the ton, one of six and one of eight inches. The largest streak at this point mills 355 ounces of silver per ton, and the smaller one from 500 to 800 ounces per ton. In addition to this there is a considerable amount of scattered mineral. A level recently commenced below this carries six inches of silver ore, and at other points in the mine there are from one to three inches of ore. Four men are employed on the property and are doing well.

IDAHO.

IREMS.—Idaho City World, Nov. 18: Charles Smith discovered a mine on a line with the Last Chance, on the Yuba side of Atlanta hill, and about a mile below the summit. It is a promising mine. Two tons of ore from the Queen's river mines, worked in the Buffalo mill recently, yielded \$100 per ton. The Yuba tunnel company have tapped the Atlanta mine at a depth of 1,500 ft from the surface. The tunnel is nearly 1,400 ft in length. The ore body tapped promises to be of bona fide size and mine proportions. Fifty-dollar ore is now being extracted. The people of Atlanta have been anxiously waiting for the tunnel to tap the ledge, and as it is now proven good at a great depth, intense excitement prevails. It is rumored that the company will erect a mill early next spring. Good ore is being taken out of the Buffalo mine. The mill was shut down a few days ago, but will be started up again in a few days. The Last Chance mine, a splendid and good rock is being taken out of it. Hall & Co. have struck rich ore in the shaft, but it is not yet known whether it belongs to them or the Last Chance company. A good deal of prospecting is being done in the mines around Atlanta.

YANKEE FORK.—A strike of very rich rock was made on the Charles Wain ledge a few days since. Recent developments on the Charles Dickens mine, a very fine ledge. Good ore is found in the lower tunnel, and a very rich strike was made lately in the crosscut at the end of the old tunnel. This leaves many thousands of good ore in sight.

NEW MINING DISTRICT.—The Idaho Statesman, of Nov. 15th, publishes a letter from Hon. V. S. Anderson, from Rocky Bar, in which it is mentioned that Merritt Kelly arrived here last week, having discovered a new mining district on Wood river, which contains a large number of ledges, one of which, a galena ledge, he says is 50 ft wide. This is an entirely new discovery, Kelly being the only person who has yet been there. The ore looks well, but no assays have yet been made. The new district is called the Black Barb, from a black-barbed Indian arrow-head which he found, and which led to the discovery. This discovery is situated on the west side of the main Wood river, and on the West Fork of that stream, between Galena City and Mineral Hill. Kelly says he has also discovered a big iron mine and some limestone. He thinks it is an important discovery, and that it will rival the other districts on Wood river. He came in to have his claims recorded, and if the weather permits he intends to return to the new district.

MONTANA.

LEXINGTON.—Butte Weekly Miner, Nov. 18: This mine has been pretty thoroughly prospected above the water level. There has been about 500 ft of crosscutting done, which may be called done work. The shaft and levels have probably more than paid their expenses, being driven mostly in ore. In some of the levels the ore body is very rich, and varies from 4 to 13 ft, some of the assays going from 200 to 1,000 ounces in silver.

GAGNON MINE.—From the west drift, 150 level, they are extracting some magnificent-looking base ore. I know it is easy to grow enthusiastic over good ore, but there is a pile on the dump which shows native silver to an extent which must do the eyes of the owners of the Gagnon good.

BECKLE MINE.—A breast of free ore eight ft wide has been struck in the west drift of shaft No. 2; eight tons of free and five tons of base ore per day.

NEW MEXICO.

GRANT COUNTY.—The New Mexican Herald, speaking of the minerals of this county, says: J. G. Mahany, who has large experience in mining and with mining men, recently returned from an extended trip through the mining camps of Arizona. With the exception of two deposits in the Tombstone district, our neighboring Territory is in no wise superior to Grant county, either in point of deposit, richness of ore, supply of wood and water or natural advantages for successful mining operations.

NEW DISTRICT.—Shakespeare is the name of a new mining district recently opened in the northwestern portion of New Mexico, close to the line of Arizona. The main ledge of the district crops from 30 to 40 ft above the surface, and can be traced for miles, and the top ores yield from 100 to 200 ounces of silver per ton. The district is coming into notice, and the inevitable newspaper, which follows the gold fever, has been the first to make its appearance. The district will be traversed by the Atchinson & Santa Fe and the Southern Pacific railroads, both of which are in process of rapid construction.

OREGON.

IREMS.—Jacksonville Sentinel, Nov. 19: Piping commenced at the Eckleson & Hamilton mining claim, on Applegate, last Monday, with every prospect of success. Magruder & Hays last week received 600 ft of 11-inch pipe for their mine on Rogue river. The pipe is now being put in position. Sturges & Beckner commenced ground-sluicing at their mines on the 10th inst. Last season they did not get to work till the 1st of March. J. H. Hyzer, Sanford Carter and John Gale discovered a rich gold-bearing quartz ledge in the vicinity of the Squaw Lake mines last week, which prospects well. The Grave Creek district and mining company have their ditch about completed and will be ready for work in a short time. The late rains have furnished water enough to start some of the mines in this section providing our miners had been prepared for it. It was not expected so soon, however, and did no good. At the quartz mine in the Willow Springs district,

owned by parties living in Portland, silver ore was discovered one day last week, assaying about \$6 per ton. A thorough prospect of this ledge is now being made.

COAL BED.—Mr. J. C. Callahan, of Coos Valley, Douglas county, has found a coal bed; the vein six ft in thickness at a depth of 49 ft. The Roschburg Independent says that this discovery proves what has frequently been claimed, that under the entire valley of Umpqua there is an inexhaustible coal bed.

NOTICES OF RECENT PATENTS.

Among the patents recently obtained through Dawey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CANS FOR HERMETICALLY SEALED GOODS.—Charles C. Lane, New Westminster, B. C., patented Nov. 11th, 1879, No. 221,468. In the ordinary process of sealing the cans after their contents have been put in, the flange or rim of the cans is crimped against the side of the can, and the can then rolled through the mechanical soldering-bath. This is simply a bath of melted solder, and by passing the can through it, the top or cover, and sides of the can are joined by the solder. Difficulty is, however, experienced in sealing the whole rim, as, while the can is being rolled, air which is displaced or expanded inside, is apt to come through the space around the rim of the cover, thus forming blow-holes, and that place where the air comes through will not be soldered, but will remain open. All cans which have this occur to them, have their contents spoiled, not being hermetically sealed. The object of this invention is to overcome this obstacle to perfect sealing. To do this, supplemental inner cover is formed which is corrugated or crimped radially and has a depression at its center into which the corrugations or grooves lead. This supplemental inner cover is laid into the can after filling, or, if desired, it may be attached to the outer cover, which has its rim crimped on the can in the usual way and in the center is formed a small hole. This small hole is made immediately over the depression in the supplemental cover, and as the grooves or corrugations all center at this depression, any air which may be in the can during this process of soldering, instead of escaping through the rim, will be directed toward the center and escape through the hole. The rim is accordingly always thoroughly soldered, there being no air to blow through the soft solder. As soon as the can is removed from the bath, a small piece of solder is put over the hole in the cover, and the can is thus hermetically sealed.

PARTIAL MANTEL GRATES.—John L. Tussler and William H. Loomis, Alameda, Cal. Patented Nov. 18th, 1879, No. 221,756. It is well known that in grates of ordinary construction it is found impossible to keep the fuel at the farther sides of the grates in a state of combustion, and that the fire is usually brightest and best in the center. It is customary, therefore, to put in fire bricks or loose brick of any kind at the two sides of the grate, so that the fuel will be confined to the center, where it will burn. The flanges formed in this grate do away with the necessity of plating bricks in the grate by confining the fire to the center, keeping out the cold air from the corners and directing the fuel to the center of the fire-place. This invention consists in the use of a peculiarly formed basket having side curved flanges and a peculiarly closed front, whereby the fire is confined to the central portion of the grate and the fuel is directed toward the center. It also consists in the employment of a cooking attachment, secured to the grate and made removable, provided with a hole or plate, by means of which ordinary cooking operations may be performed.

FINGER RINGS.—Charles M. Halsey, 131 Kearny street, San Francisco. Patented Nov. 18th, 1879, No. 221,728. In the construction of this ring an outer perforated ring is provided with a milled edge or flange, and an inner ring having characters upon it and a milled edge or flange, the edge of one of said rings having a seat or lug which fits into a groove in the edge adjacent to the milled flange of the other, for securing them together. Different designs or combinations of letters may be engraved on the inner ring, which will all show through the openings or slots in the outer one, as it is turned one way or another, one design showing at one time and another at another, as the outer ring is turned.

ORE REDUCING AND PULVERIZING APPARATUS.—Wm. Bruckner, San Francisco. Patented Nov. 18th, 1879, No. 221,773. This invention relates to that class of ore pulverizers in which the ore is placed in a drum or cylinder and crushed by metal balls passing over it as the drum revolves, and consists, first, in providing a pulverizing barrel with a grate, said grate being connected with a conveyor or arranged along the circumference of the barrel that in every revolution of the latter the ore, after being ground between iron balls, passes through the grate out of the barrel into the conveyor, by means of which it is conducted over a screen, and the coarser ore which will not pass the screen is then returned into the barrel.

VALVE FOR WATER CLOSETS.—Thomas Hennessey, Oakland, Cal. Patented Nov. 18th, 1879, No. 221,816. This invention relates to certain improvements in valves for water closets, basins and other purposes, and it consists in a novel construction of the valve, whereby it may be made extremely light, so as to act quickly, and at the same time it will resist the blows caused by the force of the water, which otherwise will indent and bruise it so as to render it useless.

Decisions in Patent Cases, Etc.

Schillinger vs. Gunther.

U. S. Circuit Court, Southern District of New York. Decided Aug. 26th, 1879. Blatchford, J.:

1. A disclaimer may embrace subject-matter set up for the first time without right in the reissue patent; and it may apply not only to the invalid claim, but to statements in the body of the specification upon which the invalid claim or part of claim is founded. The reissued specification is to be thereafter read as if the disclaimer were incorporated in it.

2. Where the statements in the specification and claim of the reissue patent which the disclaimer seeks to modify were mistakes in fact, and were founded upon experiments made after the date of the original patent: Held, that the disclaimer was lawful both to remedy the misstatements and to save the reissue from impeachment as for a different invention, it appearing that the inventor had acted throughout in good faith.

The defenses set up are overruled as not sustained by evidence, and a decree to that effect will be entered.

Williams vs. The Boston and Albany Railroad Co.

Northern District of New York. Wallces, J.:

1. Although the subordinates combinations will not produce a useful result without the addition of other parts necessary to make the complete article (a locomotive lamp), they are nevertheless sufficient to sustain the patent, because, by their co-operation, they contribute to a new result, and may be used in conjunction with such other parts as are ordinarily employed in locomotive headlights.

2. Alleged anticipations of a patented combination must show not merely the devices or elements themselves, but show them constructed and arranged substantially as in the patent, and having the same mode of operation.

3. Where the defendant employs all the parts in combination covered by the claims of the patent, infringement is not escaped, because others are employed in addition.

4. Mere delay in bringing suit for infringement is not sufficient to establish an abandonment or dedication of the patent. There must be an acquiescence in the appropriation of the right of such character as reasonably to induce the belief that the owner intended to relinquish it to the public use.

Inasmuch as complainant's patent has expired since the bill was filed, the decrees will be for an accounting only.

COMMISSIONER'S DECISIONS.

Ex-parte Hogan—Water Closet.

Interlocutory appeal from Primary Examiner. Decided Aug. 26th, 1879.

Distinct independent inventions cannot be joined, but distinct dependent inventions may, under certain circumstances, be joined in the same application.

The decision of the Primary Examiner is affirmed.

Rogers vs. Bear—Telegraphy.

Motion to re-open the interference. Decided August 26th, 1879. A motion for a rehearing will not be granted on the ground of newly-discovered evidence, unless due diligence shall have been shown in procuring the testimony. The motion is denied, without prejudice.

Thomas vs. Gutman.

Decided Aug. 26th, 1879. Interlocutory appeal. Corsets:

An issue declared in the following words, "A corset having the abdominal portion provided with incased transverse bones extending from the busks to longitudinally arranged incased bones," is ambiguous, because it is equally applicable whether there are several longitudinal bones or only one on each half of the article.

Kenerson vs. Brown and Brown.

Decided Aug. 26th, 1879. Interlocutory appeal from the Examiner of Interferences. Manufacture of wire:

Where a party to an interference, having failed to examine a witness produced by himself, whose name was not included in the list of witnesses furnished to the opposite party, because the opposite party left the place of examination, moved for an extension of time for taking testimony, in order to take the testimony of such witness, and on an appeal from a decision of the Examiner of Interferences granting the motion, the other party denied the materiality of the proposed testimony, it is ordered that additional time should not be granted, unless the opposite party should, in rebuttal, attempt to controvert the same testimony previously given by other witnesses; but that in such case a reasonable time should be assigned for supporting such testimony by additional proof.

The order of the Examiner of Interferences is modified accordingly.

Ex-parte Wiard et al.

Decided Aug. 26th, 1879. Appeal from Examiners-in-Chief. Plows:

1. The difference between an open web of diagonal bars in a plow-beam, and web of diagonal bars connected by thin plates, is not patentable.

2. A claim for a plow-beam with an open web of diagonal bars of malleable iron is anticipated

by a prior patent for a plow-beam with a web of diagonal bars connected by thin plates, the patentee having designated steel, cast iron and malleable iron in his original specification, and steel alone in his amended specification, as the material of the manufacture.

The decision of the Examiners-in-Chief is affirmed.

ACTING COMMISSIONER'S DECISIONS.

Richmond vs. Hibbard—Feather Dusters.

Motion to re-open interference. Decided September 4th, 1879.

1. Order to show cause why an interference should not be redeclared after final judgment rendered, and patent issued, granted on ex-parte motion of the defeated applicant, sustained by affidavits of witnesses setting forth newly discovered and material testimony opposed to previous findings in this case.

2. On final hearing of said order, at which all parties in interest were present, the allegations of the affiants in behalf of the moving party not being disproved or weakened by the counter-affidavits submitted, the motion was sustained, and a new interference between said application and the patent directed to be declared.

To that end a declaration of a new interference between the said application of Gilbert M. Richmond and said patent of Susan M. Hibbard is ordered.

Ex-parte Pace, Talbot & Co.—Trade-mark. Appeal from Examiner.

Decided September 17th, 1879.

1. The name "Bayard," a portrait of a United States Senator by that name, held to be proper matter for a trade mark in chewing tobacco.

2. Any proper word or phrase, whether the name of a person, firm, or corporation, or a geographical term, may be registered as a trade-mark, unless the same is descriptive of the quality of the goods, or is the name of the applicant or manufacturer, or place of manufacture, or is deceptive.

3. The name of the applicant or firm manufacturing the goods cannot be registered as an essential part of the mark.

In conclusion, it is held that the name sought to be registered by applicants is an entirely fanciful and arbitrary designation, and a proper subject of a trade-mark, but the name of the firm must not be represented as constituting an essential part thereof.

Long vs. Welsh—Trade-mark.

Appeal from the Examiner. Decided September 19th, 1879.

1. A concession of priority of adoption, use, and right of a trademark amounts to an acknowledgment of ownership by the one giving it in the one to whom it is given.

2. When one who has obtained the registration of a trademark for an entire class of merchandise is found to be the proprietor of the mark for part only of the class, it would seem that his registration was void, in view of the doctrine of *Smith vs. Reynolds*.

3. Different persons may apply for the same mark to different kinds of goods in the same class, provided their nature and resemblance are not so nearly the same as that the identity of the trade-mark would deceive the public as to origin or ownership.

4. Where the registered trade-mark covered the class of manufactured tobacco broadly, and the latter applicant confined his application to plug tobacco, the declaration, as to other interference cases, should have been confined to the issue made by the later applicant.

5. If there is not sufficient distinction between fine-cut chewing tobacco and plug tobacco to justify registration of the same mark for both kinds by different parties, then a concession of adoption for plug tobacco would be an acknowledgment of ownership of the mark on chewing tobacco.

Examiner's decision reversed.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Hillsdale, Nov. 22d, \$3,000; Northern Belle, Nov. 19th, \$5,843.14; Christy, Nov. 24th, \$6,201; Hillsdale, Nov. 25th, \$3,500; Northern Belle, Nov. 22d, \$8,811.73.

CHINESE MINERS.—The *Silver State*, published at Winnemucca, Nevada, contained, a few days ago, an item with reference to the number of Chinamen engaged at placer mining in the northern part of Humboldt county. It says: At Willow Creek there are some 25 of them at work, and there are 47 at Flat Creek. Occasionally they send 10 or 12 ounces of gold dust here by white men, but it is thought that what they send by the whites is only a small portion of what they take out. They think that if the whites knew that they were making big wages, there would be a rush to the mines, and the whites would locate what they believed to be the best part of the diggings; consequently they do not tell how much gold they get out or how rich the mines are.

A PATENT was issued November 24th for El Rincon Rancho, comprising 4,431 acres in San Bernardino county, Bernardo Yerba confirms.

QUITE A heavy snowstorm prevailed at Augusta, Ga., on the 19th.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from scouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

SAN FRANCISCO, SATURDAY, DECEMBER 6, 1879.

VOLUME XXXIX
Number 23.

The Nicaragua Canal.

The following resolution in regard to the above project, was introduced in the United States Senate by Senator Gordon on December 23, viz.:

Whereas, The project of the construction of an Inter-Oceanic canal in Nicaragua is recognized as a necessity for the prosperity of the commerce of the world and the development of the maritime and commercial interests of the United States; and

Whereas, Such enterprise must of necessity be considered of international utility under the protection of the United States; therefore be it

Resolved, That the Government of the United States pledges to accord full and entire protection to the company which shall be granted a concession by the Government of Nicaragua for the construction of said Inter-Oceanic canal, and will secure to said company the peaceful enjoyment of the rights conceded by such concession

The resolution was referred to the Committee on Commerce. Senator Burnside took advantage of the above, to call up his resolution of last session, reaffirming the Monroe doctrine in connection with the proposed Darien canal, and made a speech thereon.

A short time ago De Franco and Commodore Ammen had a long interview concerning this canal. They estimate the probable revenue for the first year at \$10,000,000. Toll would be fixed at \$2 per ton. The stock of the Suez canal, though only paying 3%, is in demand on account of the permanency of the investment. The cost of the Suez canal was nearly \$100,000,000—the same amount that it is calculated the Nicaragua canal will cost, though the general estimates do not put it above \$35,000,000. With all the inconvenience of locks, 100 vessels could easily be passed through every day, but the estimates show that if only one vessel passed through the canal every hour, or if vessels of ordinary tonnage only passed through at the rate of eight per day, the financial success of the canal would be far greater than that of the Suez route, and European capitalists would be glad to invest in it.

It is claimed that there will not be any difficulty in passing this resolution, which is considered the first step in the right direction, and will probably be followed by an authoritative announcement from a leading house in Europe, of its willingness to assume the subscription necessary for the construction of the canal. The route to be followed by this canal has been described in the report of the Commission appointed by the President in 1872, and summed up by Gen. Humphreys as follows:

Beginning on the Atlantic side at or near Greytown, running by canal to the San Juan river, thence following its left bank to the mouth of the San Carlos river, at which point navigation of the San Juan river begins, and by the aid of three short canals of an aggregate length of 3.5 miles, reaches Lake Nicaragua; thence across the lake and through the valleys of the Rio del Medio and the Rio Grande, to what is known as the port of Brito, on the Pacific coast. The length of the canal will be 180 miles, with 17 locks, requiring four and one-half days for passage.

De Lesseps, however, seems determined to carry out the programme of the Universal Inter-Oceanic Canal Company, and cut the canal at Panama, which is a level-water and deep-cut canal 45 miles long and requiring two days for passage. The cost of the two routes would be very nearly equal.

De Lesseps, in advocating the Panama route, delivered an address on the 27th of October, at the Hall on the Boulevard des Capucines, Paris, in which he declared that the climate of Panama was one of the most wholesome; that there was no fever there, and that earthquakes were unknown, which latter, operated by five volcanoes on the Nicaragua route, would interfere with the safety of vessels; and called upon the world to witness the fact that he was going to take his wife and three children with him to Panama—a positive proof that Panama was a healthy locality. But M. De Lesseps is a Frenchman, having the interests of France very much at heart. It is extremely probable that if an international canal is cut at all, it will be controlled by Americans.

Leadville Land Case.

An important case, involving in its results the title to all the land upon which Leadville stands, was lately decided by Judge Hallet, United States District Judge. The title to the land upon which the town stands and the suburbs has been derived through patents from the United States Government for placer mining grounds. The case was the St. Louis Smelting and Refining Co. vs. Thomas Kemp et al., and was brought by the company to recover leases which were purchased from the patentee, Thomas Stow, by the company, and which were taken possession of by the defendants. The court decided the patent void, on the ground that it appeared from the evidence that the patentee's tract of placer mining ground was composed of several different placer claims which he had purchased; and it did not appear in the proceedings that he had made as many different applications, had as many runnings made by the Surveyor-General, posted as many different notices, or done \$500 worth of work in all the different claims which had been conveyed to him, constituting the tract included in the patent. The case goes to the United States Supreme Court.

There is an old law maxim, frequently forgotten, which reads, "He who sticks to the letter sticks to the hark," from which the meaning is drawn that the spirit of law is of more

Assaying Cement Copper for Gold and Silver.

We are informed by C. H. Aaron, that the cement copper obtained as a by-product in the treatment of concentrated sulphurets by chlorination, contains more or less gold and silver. It also contains basic salts of iron and copper, which, if salt has been used in the roasting, are in part, at least, chlorides. The assay of this stuff in the wet way, for the gold and silver, is tedious and unsatisfactory. He has therefore adopted the following method:

A weighed quantity of the dried cement is intimately mixed with sufficient litharge to produce a lead button of suitable size, and flowers of sulphur enough to convert all the copper, iron and litharge into sulphides. The mixture, with or without the addition of carbonate of soda and borax, is put into a clay or sand crucible together with several large nails, or the nails may be added after fusion, which is perhaps better. When well fused, with a gentle heat, the heat is raised to bright red or yellow, and continued till the nails, on being seized with the tongs and washed in the slag, or rather matte, are found to be free from adhering lead. The assay is then poured in the usual manner, and the lead button cupelled. The results are very good, especially for gold. This method is suitable for other alloys of gold and silver, if the base metal is such as to be re-

Large Plows.

As an illustration of the immense land-worrying machinery, we give on this page an engraving of a mammoth plow recently built by the well-known plow makers, Deere & Co., Moline, Ill., for a Missouri railway company. It is calculated to cut a ditch 30 inches wide and 2 feet deep, and is attached to a platform car of a construction train by means of timbers framed and extending out, so that the plow cuts its ditch a sufficient distance from the track. It requires the full power of the locomotive to draw it through the soil, which is a black muck surface and hard clay subsoil. Three furrows, of 8 inches in depth, are required to complete the ditch. One mile of ditch, 2 feet deep and 3 feet wide, is made every four hours. The plow weighs 1,700 pounds, and thus does the work of 1,000 men. The beam is made of swamp oak, the toughest kind of timber, and is 14 by 8 inches in its dimensions, and of proportionate length. No handles are used, the plow being regulated in the manner already named. The landside is a piece of bar iron 8 inches wide and 1½ inches thick. It is larger than merchant iron is made, and was especially forged for this job. The share is of the best cast steel, ¾ inch thick by 9 inches in width. This is also of extra large size, and was rolled to order in Pittsburg. The top of the mold board stands 36 inches from the ground, or the base of the plow. It is made of the best cast steel, with iron lining securely bolted to the back. The plow is rigged out with an immense gauge wheel and extending cutter. It is said that its performance is entirely satisfactory to the railroad company.

The relative size of this plow can be judged by the common sized one, which stands near it in the engraving, and by the height of the stocky individual who seems to be in doubt whether the beam is quite true.

The facts about this great prairie plow are of course interesting, but we are sorry to see it claimed that this railroad plow is the "largest plow ever built." Nearly two years ago there was another large railroad plow constructed and it too was claimed to be the largest ever built, etc. The fact is that both these giants are less in

size than a California plow, which we have described before, but which we allude to again in this connection. A few years ago a plow was built on the Livermore ranch in Kern county, according to the design and under the supervision of Mr. W. H. Souther, which, if it should meet this Iowa plow, it would serve it as a locomotive might a hand-car. It is called the "Great Western," and these are its weights and measurements: Beam, 18 feet long, 18 inches deep and 10 inches thick; landside, 17 feet long, 5 inches wide and 1½ inches thick; standard, 3 feet high; mold board, 12 feet long and 3 feet high. This plow weighs one ton and is swung by a heavily ironed wooden arch, between two wheels eight feet in diameter and with tires six inches wide. The attaching of the body of the plow to this arched axle of the wheels is accomplished by running two heavy fenders back from the arch, and fastening them to the back end of the beam and mold board. A 14-foot lever runs from the mold board across the back end of the beam, and on this a man stands to adjust the plow as to depth of cut, etc. The "Great Western" cuts a furrow four feet wide and three feet deep, and is drawn by 80 oxen, yoked to a wire cable one inch thick. This cable weighs 1,140 pounds.

There follows the plow an A shaped scraper, drawn by a chain from its apex by 80 mules. It is 12 feet wide and 3 feet high at the open end. The sides are heavy iron. This, following the plow, above the furrow out 10 feet from the place it is left by the plow.

An effort is making to create a great exporting and importing point for the South and West at Port Royal, S. C.

PLOW FOR RAILROAD DITCHING MADE BY DEERE & CO., ILLINOIS.

moment than the mere wording or technicalities. It is upon these technicalities that claim is made to whole cities and towns, not always in the hope of succeeding, but often in the hope that property owners will pay a certain amount to get rid of a law suit. We do not know whether this Leadville case is of a similar nature, but the fact is patent that when a growing city like Leadville is sought to be swallowed up by any individual or corporation, after vested rights have accrued, there is something else besides mere justice sought.

THE STOCKTON INDEPENDENT.—We note with interest the purchase of the Stockton Independent by Messrs. Worley and Milne, formerly of the San Francisco Bulletin, the former as an editorial writer, the latter as foreman of the printing department. Mr. Worley is a journalist of excellent repute, well informed concerning the industrial interests of the State, a writer of marked ability, and a man of zeal and action. The Independent is one of our best interior papers, and occupies an important field. Under the new proprietorship it will be fitted to go farther forward, impelled by a fresh infusion of newspaper ability, nerve and industry. A good newspaper is a great advantage to any community, and this fact will doubtless be shown in the future of the Stockton Independent. Its work will be of much importance at this time in the development of the great San Joaquin valley, and the people of that part of the State can hardly give too strong a support to the paper under its new management, because we believe their work will fully justify our expectations of it.

duced with difficulty or not at all from the sulphide by iron.

Arcenic and antimony, though reducible, will be again taken up by the iron. Zinc is not easily reduced, and is volatile. Tin would probably prove troublesome.

The method also answers with copper ores containing gold or silver, and is convenient where the ore is of such a character that a good deal of copper comes down with the lead in an oxidized assay.

Massive metal should be reduced to powder by filing or otherwise.

A NEW RAILROAD SIGNAL.—On Wednesday last the Southern Pacific Railroad Company placed in position, at the intersection of the railroad and Valencia street in this city, a pneumatic bell or annunciator for the signaling of approaching trains. The invention, patented by the Pneumatic Manufacturing Company, is for the signaling of trains at any distance from 500 to 1,500 feet, and every car wheel passing over a lever affixed to the rail rings a bell in the station house. The fall of the lever compresses the air in a cylinder to which it is attached, and the compressed air escapes through a tube in communication with the bell at the depot. The invention will undoubtedly prove of the utmost value.

ANOTHER attempt has been made to assassinate the Czar of Russia while on his way from Berlin to Moscow.

A MINOR state of siege still exists in Berlin.

We admit, unendorsed, opinions of correspondents.—Eds.

The Divining Rod.

EDITORS PRESS:—Your article in the PRESS of the 17th inst. reminds me that I once investigated this subject to some extent. I think you handle the matter much too tenderly. It is my opinion that it is not at all a delusion on the part of the operators, but simply a fraud.

Hearing of Mr. Peck from an acquaintance who believes in the miraculous rod, I called on the gentleman, who was obliging enough to show me the instrument and to give me an exhibition of its use (?). As, however, Mr. Peck said that it would only work in his own or his brother's hands (why so?), it was useless for me to experiment with it myself. The discussion of the subject, however, soon elicited the information that there was another gentleman with another divining rod, which, being less fastidious than that of Mr. Peck, would work in the hands of even so unworthy a person as myself.

Accepting an invitation to join a party of four or five, I went to see this gentleman, whose name, under the circumstances, it might be uncourteous to reveal, wherefore I will simply designate him as Mr. H. On reaching the residence of Mr. H., we were ushered into a small but well-furnished sitting-room, in one corner of which was a piece of furniture with several lumps of silver ore upon and under it. After some conversation, the rod was produced. It was similar to that described by you, which, as already stated, I had also seen. The bulb, however, differed slightly in its construction, and we were informed by Mr. H. that it was the subject of a patent (?). A \$20 roll of silver coin being laid on the floor, Mr. H. proceeded to walk over it, holding the rod in his hands, with the bulb directed toward the ceiling. As soon as Mr. H. stood directly over the coin the rod turned in his hands, pointing downwards, Mr. H. apparently resisting the movement with all his strength. I then made the experiment myself, but without any result, the same thing happening to some others, while with one or two it was successful. I then requested Mr. H. to repeat the operation, which he did, while I watched him narrowly. Again taking the rod in my hands, I walked over the roll, and lo! the rod turned downward in spite of my manifest effort to retain it in its original position.

This was so far satisfactory to all, myself included, but it was thought advisable to test the wonderful properties of the magic wand by making it the means of discovering treasure which was not exposed to the view of the operator. Accordingly, Mr. H. retired from the room, crossing a passage to another room, and the company proceeded to consign purses, watches, and other valuables, to the recesses of a felt hat, which was then concealed, after which Mr. H. was recalled and requested to "locate" the treasure. After going several times around the room, Mr. H. announced that the valuables were in a place where they were not, but he attributed his failure to the fact that a safe containing money was located in a room below, and exactly under the place which he had indicated, so that after all it was not exactly a failure, inasmuch as he had really found a treasure, though not the one of which he was in search.

Of course a "new deal" was accorded in simple justice. On the second return of Mr. H. from temporary banishment, he again made the round of the room several times, during which the rod pointed strongly in various places, until at last, after the manner of the German philosopher who discovered "pantogen," to wit, "by a series of successive approximations," Mr. H. was able to indicate the precise spot where the treasure was concealed. This being unanimously voted a success, we carried the investigation further. A gentleman held the rod a few inches above a large and rich piece of ore, and assured us that he could distinctly feel an attraction. My nerves were perhaps less sensitive, I could feel nothing, and on the former gentleman repeating the experiment with the additional circumstances of my holding a hat before his eyes, while another held the piece of ore sometimes above, below, or on either side of the bulb, the gentleman's guesses as to the position of the ore were invariably and unaccountably erroneous. Other trials gave similar results.

I will not attempt to explain the success of Mr. H. in finding the hidden treasure in his second trial, but will simply mention some little circumstances which I observed, and leave each to form his own conclusions.

Shortly after our arrival, before the performance began, a couple of gentlemen dropped in "quite promiscuous." These gentlemen were strangers to our party, but were acquainted with Mr. H. They remained in the room while we hid the gold. Being middle-aged gentlemen they had probably forgotten all about the childish game of hide and seek, or "now you burn, and now you freeze."

While Mr. H. was in retirement, no one had

the rudeness to offer to stay with him to see whether he remained in the room at the other side of the passage or not.

The manner of holding the rod is peculiar. It is, as you remark, bifurcate, consisting of two slips of whalebone, connected to a sort of hulk or receptacle containing something or nothing, as the case may be. The two handles are not grasped straightforward and honestly as one would take hold of a pair of tongs to lift some light object, but in reverse fashion, with the ends projecting between the thumb and the first finger. Then by turning the hands so that the thumbs are outward, and consequently the finger nails upward, and drawing the hands apart, the slips of whalebone are subjected to considerable flexure, and by a slight movement of the wrists, the hulk is thrown upward.

In this position the ends of the whalebone project slightly from the hands, and spectators are requested to seize one of these ends with the thumb and finger, and try to prevent the downward movement of the rod when pointing to treasure, which it is, however, very difficult to do, because the flexure of the slips in the hands of the operator, give him a great leverage against the thumb and finger of the spectator, who can use no other force than a comparatively feeble torsion of the small projecting end of the slip.

Holding the rod as described, it will be found that a slight movement of the wrists will cause it to turn up or down with considerable force. This movement of the wrists is hardly perceptible, and is effectually disguised by the squirming and straining of the operator in his apparent effort to resist the turning of the rod.

As I have intimated, I found no difficulty in making the rod point up, down or sideways as I wished, though apparently of its own accord and even against my efforts.

As a finale, one gentleman was invited to walk across the street with the rod in his hands, and to notice any attraction which he might feel. He felt nothing, but Mr. H. assured us that a vein of copper existed under our feet, and in his hands the rod did not fail to indicate the fact.

C. H. A.

Spruce Mountain District, Elko County, Nevada.

EDITORS PRESS:—The question is often asked, particularly by capitalists, where can we go to make a safe and remunerative investment in mining property, to which I will endeavor to answer in such way that it may be of interest and benefit to some of the inquiring minds and readers of your most valuable paper. To all such I would say: First, look for a district where there is no excitement, but where everything is quiet, or, as generally called, *dead*. Next, see if there are any mines in that district sufficiently developed to prove beyond doubt their permanency; also that the quantity and quality of ore is sufficiently good to justify and guarantee a profit in working them. Next, see what the facilities are, such as timber, water, furnace site, etc., for working said mines; also, the distance it is to railroad, which is an important item. Then, if all things are found to be favorable and satisfactory, see if you can buy the property at about one-half less than you would have to pay for it if it was located in a lively camp where everything moves with the tide of excitement. If you can, then in that case I would advise you to do so at once, and then get up a little excitement of your own. That is where the musical part of the programme comes in, and no one can say that it is not honorable or legitimate.

Now then I will say to all capitalists, who wish to invest in good mining property to good advantage, come to Wells, Nevada, and I am confident that you can find mining property that will suit you. I will give you a short description of a group of mines that I visited and examined this fall. They are situated on the eastern slope of the mountain and dip to the east. The chief of this group is called the "Black Forest." It was located in June, 1872, since which time the discoverer (also present owner) has opened and developed it by three tunnels run into the mountain side at different levels, all cutting the ledge and showing large bodies of good ore. The tunnels are connected by inclines run down on the dip of the vein, which gives perfect ventilation through the mine. The inclines also shows large bodies of splendid ore from within 20 feet of the surface to the lower level, which is over 300 feet deep on the dip, the vein dipping at an angle of from 45° to 50° to the east. The hanging wall is white lime and the footwall diorite, under which lies porphyry. The course of the vein is north and south from the lower tunnel. There are two inclines run down on the ledge, making a total depth of about 340 feet. At the bottom of this incline there is to be seen a large body of beautiful gray and yellow carbonate. It was a strike made last spring. The mine is sufficiently developed to show permanency beyond all doubt; and the quantity and quality of ore could not help but please the most fastidious eye. I should judge that there are from 8,000 to 10,000 tons of ore developed and left standing in the mine, and at least, 600 tons out on the dumps. Judging from some 20 assays shown me, from all the different kinds of ore in

the mine, I think it will average from 40% to 45% lead, and from 40 to 50 ounces in silver per ton of ore. The ore is pronounced to be free smelting ore, and if it averages 40% lead, two and a half tons of it will yield a ton of bullion, as there should be no loss in smelting such ore, and at that rate, at the present price of lead, the lead value would more than pay all expenses of mining, hauling, smelting and freighting the bullion to New York market, as the ore can be extracted and placed on the dump at a cost not exceeding \$1.50 per ton, and hauled to the furnace for 50 cents per ton, and smelted at a cost not exceeding \$7.50 per ton (after furnace and coal kilns are built and ready to run), and the freights on bullion from furnace to New York will cost about \$60 per ton. The facilities for working the mines and ore in this camp are all that could be desired—plenty of timber, wood and water. This camp is situated 35 miles south of Wells station, on the Central Pacific railroad. There is a good wagon road from the mines to the railroad. To all who are inexperienced in mining I would say get a practical and reliable expert to come with you to examine the mines in this district for your own satisfaction, and do not depend upon hearsay, as I am aware such is very uncertain; but come and deal direct with the original prospectors, discoverers and present owners of valuable property—by so doing you will find a golden harvest ready to reap.

I will add from good authority that the snow never falls deep enough during the winter to interfere with business. This district and mountain is beautifully located; it being surrounded by fertile valleys and foothills covered with the finest quality of bunch grass, on which thousands of cattle keep fat all winter. The name of this district is "Spruce Mountain," and it is situated in the southeast part of Elko county, Nevada.

OLD 49ER.

Wells, November 22d 1879.

"Pliocene Man" in California.

EDITORS PRESS:—I notice in your issue of November 8th an article under the head of "Pliocene Man." Reading said article brings to mind the days of '49. I will copy a portion of the article, beginning near the bottom of the first column, as follows: "The discoveries in California, India and elsewhere seem clearly to indicate that the human race must have existed, over a large portion of the world at least, for an immense period of time, in the primitive condition, that is, at the lowest possible stage of humanity—civilization it cannot be called. So far as California is concerned, the evidence all points in this direction. The implements, tools and works of art obtained are thoroughly in harmony with each other, all being the simplest and least artistic of which it is possible to conceive, whether found in the strata under the basaltic lava, or above, at any point in the detritus, we always recognize the same type."

Here let me give you some evidence which may interest many of your readers. I think it will agree with some of Prof. Whitney's conclusions, and differ from some of those drawn in that part of the article above copied. The proposed evidence is as follows: It was in the month of October, 1850, I, with several others, was mining in California, on the Middle Fork of Feather river, four miles below the mouth of Nelson creek, on what was known as Rich bar, and sometimes called "Volcano" bar. On the top of the mountain about one mile north of said bar was evidently an old extinct crater. We had worked the pay dirt and gravel off of said bar, under which there was a stratum of cement or lava. One day, out of curiosity, four of us sunk a hole about four feet square down through the lava, which was about five feet thick. Under this was a stratum of gravel about one foot thick. This we panned, but could not find any gold. Under the gravel we came upon granite bedrock, and on the granite found an old pick. It was in size and form as near like the picks we were using at that time as it well could be; the eye was the same shape (largest at the outside); it was also worn very blunt. We looked it over and laid it on a pile of rock, one of the boys remarking that we had found old King Solomon's mining camp in the land of Ophir. This evidence shows that California must have been inhabited by civilized man, who had some knowledge of the arts and sciences, previous to the cessation of volcanic activity in the Sierra Nevada, as it was evident that that pick had been used and left there before the lava spread over the surface of the bar and side of the mountain. It is also evident that whoever made and used it had a knowledge of the precious metals, showing conclusively that as far as California is concerned, the conclusions drawn in that part of the article which is copied above are not quite right, as I think Pliocene man is entitled to more credit than that conclusion gives him.

F. F. BEARDSLEY.

THE British Consul at Panama reports that india-rubber has almost ceased to be an article of export from the isthmus, mainly in consequence of the great difficulty and expense of getting at the trees in the remote districts of the interior. Those nearer the coast have been destroyed by the wasteful system pursued by the natives in cutting down the trees to procure the sap.

The Black Hills, Dakota.

An interesting letter from Central City, Dakota, was lately published in the Grass Valley Union. The letter is from James Gluyas to W. H. Mitchell, of Grass Valley. The writer has been at the Black Hills about two months, and describes that region as the highest quartz mining country he ever saw. He says:

"The ledges, or what we call the high champagne lodes, are running through the hills in every direction and are from 40 to 130 feet from foot to hanging wall, and 10 men can keep a 60-stamp mill running from month to month. There are three mines here working with open cuts through the hills, and the Homestake company is running 200 stamps, and putting in 120 more, when they expect to crush 800 tons per 24 hours. The Homestake crushed for the month ending September, 18,000 tons of ore, and cleaned up \$75,000. So you see it is not much more than \$4 per ton. The Homestake uses a locomotive to run its ore from the open cut to the mill. In our claim we have two lodes; one is 40 feet from wall to wall. In the eastern ledge we are in 125 feet, and no signs of hanging wall yet. We are only running 20 stamps at present, but are putting up a new 60-stamp mill. The machinery is on the ground, and we expect to start up by the 1st of January.

"There are about 1,500 head of stamps running here, within a distance of three miles. The lodes are slate and quartz, and quartz and slate, from wall to wall, and when you look at them as a whole they appear like big cinnamon lodes. The gold is very free in the rock, and nothing is used for saving but copper plates at the batteries—no pans. The ore is very red, and when the men come off shift they look as red as 'rats'—all same old country. We work our mine through two tunnels, and have about 200 feet of backs. Miners' wages, \$3.50 per day; carpenters and blacksmiths, \$5, and there are hundreds out of work. Flour is \$8 and \$10 per 100 pounds.

"So much for the mines. The Black Hills are from 500 to 1,000 feet in height, about 50 miles wide, and 100 miles long. Between the hills are very fine ranches, where they can grow any amount of vegetables. There are three little towns here, Deadwood City, which is three and one-half miles distant from the mine, Central City and Lead City, each about one mile distant. In all they contain about 12,000 inhabitants, chiefly Eastern people.

"There is no gold coin in circulation here, the currency being all greenbacks. The climate is peculiar. There seems to be no summer. The wind blows as it does at Virginia City, but the climate is not as good. Some days we have a burning sun, with a cold and chilling wind, and at the same time freezing. The weather will sometimes change four and five times a day—with rain, snow, freezing, hot and sultry, all in one day. Of course this makes sickness, and every boarding-house contains several sick men.

"Central City is about 1,500 miles northeast of Colfax, and the cost in coming from there, in fare and living, is \$130 (\$75 from Colfax to Sidney by rail, and \$40 from Sidney to Deadwood City by stage, a distance of 300 miles), being six days on the way, three days and two nights of which are in stage."

An Island Belching Hot Water.

A late issue of the London Telegraph contains an account from the Lower Danube of the alarming intelligence respecting the strangely abnormal condition of earth's crust in those wild but lovely regions where the rugged Carpathians constitute the Roumanian-Hungarian frontier. These mountainous districts were terribly convulsed by the earthquake reported some days ago from Eastern Europe; and the Island of Babagay, which lies in mid-Danube, off Moldova, not far from the Iron Gates, and in close proximity to the tumultuous rapids that agitate the breast of the great river from Orsova to Drenkova, has been the scene of some extraordinary phenomena, which have stricken its inhabitants with panic. During the earthquake a huge gulf was rent in the surface of the island, and promptly emitted an enormous column of scalding water, by which a considerable portion of Babagay was within a few hours inundated. On Sunday, the 18th of October, this destructive geyser ceased to spout as suddenly as it had commenced, but when the vast gap whence it had flowed was dried up it was observed that several ragged-edged craters had formed themselves at the bottom of the drift. These craters have ever since, at brief intervals, vomited hot earth and black sand in large quantities, and apprehensions are entertained that either the island will altogether disappear, or that it will become the site of a permanent volcano. A little further up the river, the picturesque ruins of Golubacz Castle, an ancient feudal fortress, built upon the remains of a Roman stronghold, have been completely demolished by the earthquake, which has also filled up the gloomy caves in the rocks beneath Golubacz. These caves were credited, or rather discredited, as the chief breeding places of the malignant mosquitoes that infest the Danube and its banks between Basiach and Turno-Severin. Their destruction, therefore, is a legitimate source of exultation to the riparian populations. Not so the development of volcanoes and boiling springs in the neighborhood of countless Wallachian and Servian homesteads.

MECHANICAL PROGRESS.

Signaling in Mines.

T. A. Edison and Jesse H. Burnell, a New York electrician, are engaged in working out the problem of signaling between the lower levels of a mine and the engineer on the surface; also, sending signals to the engineer from a cage while ascending a shaft. Mr. Edison is of the opinion that they will be able to do all that is required.

In the meantime I. E. James, Superintendent of the Yellow Jacket, proposes a plan which is very near the mark as regards simplicity and effectiveness. His idea is to run a gas pipe from top to bottom of the shaft, the upper end terminating in a microphone placed alongside of the engineer. On the side of the cage there is to be carried in a suitable scabbard a piece of iron rod of a convenient length to be used in striking upon the gas pipe. Even now, without any microphone or other sounding arrangement, the miners are in the habit of signaling long distances by striking with a hammer upon the iron pipes through which compressed air is conveyed.

As regards the sending of electrical signals from cages, or even of talking from them while in motion, we are of the opinion that there are no great difficulties in the way. An iron or steel arm might be extended from the cage to slide up and down the edge of the wire, in the shape of a flat strip of metal, in such a way as to keep those on the cage in constant communication with the engineer and his apparatus above, through an unbroken electrical circuit.

At all events, whether or not this plan would answer the purpose, we do not doubt that we have on the Comstock mining engineers and machinists who are sufficiently ingenious to satisfactorily work out this signal problem. The ordinary signal rope does very well to a certain depth, but at length a point is reached where the weight of the rope becomes so great that it is hard work for one man to make the signals, and what seems a heavy surge on the rope may, after all, lack force to strike the bell. It is owing to this that the signals sometimes fall short in the number of bells struck.

As the man who pulls a rope in one of our deep mines cannot hear the bell strike, he has no guide in the business of signaling except the amount of force he has used, and it must often be a nice point to decide between what outlay of strength would strike the bell and what would fall short.

Instrument for Measuring the Inclination of Bore Holes.

A useful instrument, says the *Colliery Guardian*, has lately been invented in England, by G. Nolten, of Dortmund, for ascertaining the inclination of bore holes from the perpendicular and for indicating the direction of the inclination. It is well known that bore holes, especially those made with turning tools, are seldom perfectly perpendicular; yet, although it is of the greatest importance to ascertain the amount of this deviation where it is desired to know the exact vertical depth bored, no instrument had been devised for giving such indications until the invention here referred to. In stating the depths of bore holes it is generally assumed that they are perpendicular. In some cases, however, the inclination is sufficient to cause considerable error in calculating the distance of seams from the surface and the thickness and dip of strata.

The action of Mr. Nolten's instrument depends upon the fact that liquids always seek their natural level. The inventor employs a ground, flat-bottomed, colorless glass vessel, the sides of which are exactly at right angles to the bottom. This vessel he half fills with a mixture of one part of hydrofluoric acid to four parts of water. The acid, having the property of etching upon glass, leaves a permanent indication upon the sides of the vessel of the level of the liquid. If the instrument be placed in an inclined position, and if it be kept still for half an hour, the level will be marked in the shape of a ring upon the glass, which is formed in such a manner that exactly at the level of the liquid the inner part of the glass towards the bottom will be etched to the extent of one-tenth of its thickness. Some of the liquid is then taken out, so that its level in a horizontal position will mark itself below the lowest line of the first mark. The glass is then placed upon a perfectly horizontal surface, and being kept in this position for half an hour, the liquid makes another mark. By pouring out the liquid and cleaning the glass, the two marks will be seen clearly, while the glass will remain perfectly transparent. In practice, the glass is placed in a water-tight instrument, having the form of a round-ended cylinder, with a rod passing through the top, by which it is secured to the bore-rod or rope employed for lowering it. With the exception of the gutter-percha flanges, which prevent it from falling heavily when being lowered, this instrument is made entirely of brass, on account of the magnetic needle which is enclosed. The glass vessel containing the etching fluid is closed with a lid and placed in the interior of the cylinder upon a plate which is set exactly at right angles to the sides of the cylinder. The instrument is then suspended in the bore hole at any depth where an observation is to be taken, and after the

manner before described the angle of deviation from perpendicular is arrived at. This result being obtained, there now remains to be found the magnetic bearing of this deviation in a horizontal plane. For this purpose the glass containing the etching fluid is fitted into a ring which is in rigid connection with a compass, and is divided into degrees, etc., similarly to the compass. If this connection, of which the glass with the ring and the compass are parts, is inclined in any direction, whereby the line of inclination is found by means of the liquid in the glass, the direction in a horizontal position of this line is read off by the division on the ring in which the glass is set, at the same time reading the compass, then the difference of these readings will be the magnetic bearing of the line of inclination. In carrying out this method in practice, it is necessary that the reading of the magnetic needle in the bore hole should be the same when the instrument is brought to the surface, so that the bearing may be read. This is accomplished by fastening the needle in the bore hole, allowing it first time to settle by means of a watch forming part of the instrument.

The value of the invention has been proved in practical working in five bore holes at which it has been employed. It has also undergone many experimental trials, with the result of fully confirming the accuracy and reliability of its indications.

MACHINE MINING IN NORTH WALES.—A few days ago a number of gentlemen assembled, upon the invitation of Mr. Edward Williams, J. P. of Wrexham, to visit the immense underground working at the Park Lead mines, and especially the level now being driven with Schram's rock-drills to intersect the lodes. The Schram drills are working very satisfactorily, and the professional gentlemen present, who carefully examined them, pronounced both the machines and the work they were doing as excellent. Both Capt. S. Michell and Mr. Williams displayed the utmost readiness to give information. With one of the 2½-in. Schram drills, worked by an 8½-in. compressor, 14-in. stroke, with 30 lbs. of air pressure, the results were—Distance driven, 18 ft., at an average of 3 ft. per day, at a cost of £7 per fm., the miners paying all cost—as dynamite, fuse, candles, etc., and at this price the men put the debris into the tubs and took on at the bottom of the shaft. By hand labor the driving of the ground would have cost £10 per fathom, and six men would not have driven more than 3 fathoms in a month. It is thus seen that six times the quantity of work is done for 30% less wages, which is more satisfactory as the rock is hard and troublesome, and is very fatiguing to work by hand labor. At the conclusion of the inspection an interesting discussion upon mining generally took place, in which Mr. Williams, Captain Ellis and Mr. Reed (Hendre Mines), Mr. Lester (Miuera), Captain Michell and others, took part, the general opinion expressed being that both drill and compressor worked admirably. The Schram drill has also been started this week in the Llanrwst district, and it is believed that as soon as the machine becomes better known it will be widely adopted. —*London Mining Journal*.

METAL MOLDING MACHINES.—Within suitable standards Mr. C. H. Taylor, of Leeds, proposes to mount and fix a horizontal plate, and below this in suitable bearings he provides a rammer or plunger of a similar construction to the bottom plunger on a brick machine. A vertical adjustable motion may be imparted to the rammer or plunger by a cam, crank or other equivalents, actuated by some suitable motor. Between the horizontal plate and plunger or rammer he passes a round table, on which are mounted the molding boxes, and within the table is provided a model or pattern to form the desired mold. In the first place the pattern or mold forms the bottom of the box, and in this manner it is passed under a hopper, when simultaneously with the passing under of the box a sliding door is opened at the bottom of the hopper to allow sand to pass therefrom into each molding box, which after being filled is brought between the horizontal plate and the vertical rammer or plunger; when in this position an upward movement is given to the rammer or plunger which lifts the patterns or models up into the sand, at the same time by the assistance of the horizontal plate imparts sufficient pressure to solidify the sand into which the pattern or model is impressed ready to receive the metal. This being done, the box is passed from between the horizontal plate and plunger or rammer, taken off the table and ready for use. Each box in its turn may undergo a similar process as regards the filling and the pressing operations. The table on which the molding boxes are carried may be moved either by the attendant, or from some suitable motive power provided with a stop motion. —*London Mining Journal*.

UTILIZING POWER.—A new invention has been tried with success in London in the utilization of the power generated in stopping street cars for the purpose of re-starting them and thus saving the extra exertion of the horses. The contrivance is a coiled spring, which is wound up by the stopping of the car, and which, when released, acts on the wheels so as to impart motion. It acts, too, as an assistance to horses up a steep grade, the power having been acquired in a preceding down grade and kept stored in the spring until the energy is required.

SCIENTIFIC PROGRESS.

Important Advance in Metallurgy.

In the "World's Work" of the November issue of *Scribner* occurs the following interesting and important item on the recent discoveries made in metallurgy:

"Some recent researches into the behavior of metals under the influence of heat, as in annealing, have led to discoveries that may bring about important changes in the present methods of obtaining commercial shapes of metals, wires, rods, bars, etc. The search for a metal that might be used in electric lamps giving light by incandescence led to experiments on platinum wire under repeated heating and cooling by electrical currents. A piece of platinum wire was brought to a white heat and kept there for some time, when it was cooled and then examined under a powerful microscope. It may here be observed that this heating was practically annealing, and the result throws a new light upon this old and important process. To the touch the wire was soft and yielding, practically annealed wire. Under the glass the wire was seen to be full of cracks, chiefly of an rhombic form, branched and running into each other in every direction. The heating results in a kind of rupturing or cracking open, and in seeking an explanation of this, it was thought that in bringing the wire suddenly to a white heat, the air held both physically and mechanically in the wire was expanded and exploded, tearing its way out and leaving fissures and cracks all over the surface. These fissures are plainly visible and assume the torn and ragged appearance that might come from such explosions of the contained air. The wire, before stiff, is now soft and yielding, simply because it is cracked and bends readily at every break on its surface. To illustrate this we have only to paint a sheet of paper with a gum like dextrine or even mucilage. When the paper is stiffened draw it over a sharp edge and crack the gum, and the paper will bend freely in every direction. Here the cracks are visible and it is easy to see that they allow the gum to bend. It may, from this, be seen that annealing is a rupturing or cracking of a metal, and that its softness and pliability result from the free play given by the cracks. This discovery at once led to a more important step—the repeated annealing of metals in a high vacuum. A strip of platinum was placed in a small glass tube by melting the glass over the wire at each end of the tube and thus enclosing a portion while the two ends were left exposed. This wire was then connected with a battery, and when a high vacuum had been obtained by means of a Sprengel pump, the wire was brought to a dull heat by means of the battery. It was allowed to remain heated for a few seconds and then cooled. This heating and cooling was repeated many hundred times in the course of ten minutes. Though the process through which the wire passed is not visible, it can be imagined to be somewhat like this: The sudden heating of the air held in the wire caused it to expand and tear its way out, leaving the wire cracked in every direction. The cooling of the metal produced a contraction tending to close up the ruptured fissures, and, as it were, to knead together the particles of the metal. The vacuum assisted the air to escape from the metal by making a difference in the internal and external pressure, and undoubtedly hastened the process. At the end of ten minutes the power of the battery was increased slightly and the heated wire showed a pale red. The alternate heating and cooling at this temperature was kept up for ten minutes and then another advance was made in the temperature. In this way the wire was heated and cooled (practically annealed) for five hours till it was raised to a vivid white heat. As the process went on it was found that the metal passed beyond its melting point and remained intact in temperatures far above those at which in free air it had melted. On the completion of the process the wire was found to be intensely hard and elastic and of a silvery brightness. Under the glass it showed an absolutely unbroken surface, polished like glass and smoother than any wire obtained by the usual processes. It would seem as if this repeated annealing in vacuum had kneaded and compacted the metal, making it more dense than any known metal. It is now as elastic as steel, and, coiled in a spring, retains its elasticity even when at an extreme white heat; furthermore, it can no longer be annealed. The metal appears now to be in a new state of which we had no previous knowledge, and for electric lighting purposes it is practically a new metal with new properties. Experiments with iron and other metals in the same manner produced like results, though of course in a varying degree. All the experiments that have led to these valuable discoveries have been performed upon a limited but practically commercial scale because the pieces of wire treated are only required to be very short. For treating iron rods and bars it is proposed to carry on the annealing in wrought-iron tanks from which the air is exhausted by steam power. For small wires and short rods a current from a Faraday machine (this is the new name proposed for dynamo-electric machines) would be sufficient. For larger masses of metals heating in a furnace would be required, the metal being raised to a temperature a little short of fusion and then allowed to cool in a vacuum. Even one annealing would tend to

compact and harden the metal, but repeated heatings would, undoubtedly, give iron new properties, of which we can now have no adequate conception. It may here be observed that annealing in free air tends to soften metals, for the reason that has been given, that is, cracking; whereas this new method of annealing produces in time just the opposite effect. Metals are harder and entirely changed in density and appearance and in their behavior under heat."

HOW RAILROAD TIME IS OBTAINED.—An exchange says: The Pennsylvania railroad and all its divisions and branches are furnished Philadelphia time by Prof. Langley, of the Western Observatory, in Alleghany, Pa. Two main clock in Chief Telegraph Operator Suter's office, in the Superintendent's department of the Union depot, is connected with the observatory solar clock by fine electric wire, and every vibration of the pendulum of the solar clock is announced by the tap of a small bell in Mr. Suter's office. The pendulum in the Pennsylvania railroad clock must keep pace with the bell, as in case of failure the pendulum is at once re-adjusted. The solar clock in the observatory is regulated by a sidereal clock, or a clock regulated from fixed stars. The bell is tapped by electricity through a wire connected with a wheel on the second hand of the solar clock, upon which there are 60 cogs, each cog indicating a degree of the sixtieth part of a second. Ten of these cogs are filed out of the wheel, for the purpose of breaking the circuit, and consequently ten taps of the bell are lost every minute. This is done in order to give the operator a start on each minute, and at the end of an hour one minute and ten seconds are not recorded on the bell. At four o'clock each afternoon Operator Suter takes his position at the clock battery and sends the time, as near as science can give it, to Blairsville, Altoona, Columbia, Philadelphia, etc., the Philadelphia and Erie railroad, the Northern Central, and the eastern connections and branches. At five o'clock p. m. the time is given to the different offices by single and double taps of the company's telegraph wires. The same service is given to Columbus, O., and other Western points, and the time is there computed to suit the locality.

EARLY IRON MAKING IN ENGLAND.—In the reign of Edward III, iron was so scarce that the pots, spits and frying-pans of the royal kitchen were classed among the King's jewels. Up to the end of the fifteenth century, English iron was not only dearer, but inferior to that manufactured on the Continent. During the fifteenth century the manufacture of iron began to be extensive in Sussex, where the ore and timber for smelting it abounded, and iron mills soon became numerous in the country. The landed proprietors entered into the business eagerly, and not only were many ancient houses enriched thereby, but several new men acquired wealth and founded families. In the forest of Dean, also, where wood was plentiful, iron was largely smelted. The land, however, soon became denuded of trees in consequence of the exclusive use of charcoal for smelting; people were alarmed, and many edicts were promulgated restricting the manufacture of iron. Eventually the feeling became so strong that from the time of the Restoration iron manufacture of England rapidly declined. Coal was known, but there was a prejudice against its use on account of its supposed pestilential qualities. Coal, moreover, as then used, injuriously affected the quality of the iron, and it was not till the beginning of the eighteenth century that the first real steps for overcoming the difficulty were taken.

MOLECULAR CONSTITUTION OF LIQUIDS.—R. Pictet has shown that in solid bodies there is a simple relation between their atomic weight, their length of calorific scintillation, and their temperature of fusion. This relation is a consequence of the universality of the laws of attraction, and of the most simple representation of the temperature, regarded as the amplitude of the calorific oscillations. On passing from the solid to the liquid state, each solid molecule should contain at least two liquid molecules. Since the molecular cohesion of all bodies is equal at the melting point, on departing from that point the length of calorific oscillation should be functions of molecular masses for equivalent aberrations of temperature. If we compare all liquids at their boiling points we should be able to deduce the same numerical formula as for solids. Pictet confirms these views by a comparison of theoretical and observed results in 23 solids and 16 liquids.

TEMPERATURE OF THE SUN.—Newton, Waterson, Ericsson and Sencchi have asserted that the sun's temperature cannot be less than from 1,000,000° to 2,000,000° (1,800,000° to 3,600,000° F.); Pouillet, Vieoaire, Violle and many others, maintain that the temperature cannot exceed from 1,500° to 2,500° (2,700° to 4,500° F.). F. Rosetti discusses experiments and methods of his own, from which he concludes that the temperature cannot be much less than 10,000° (18,000° F.), or more than 20,000° (36,000° F.).

NUMBER OF OSCILLATIONS IN A MUSICAL NOTE.—Pfaundler concluded, from observations with a siren, that two oscillations were sufficient to produce a note. Felix Aernbach, from a combination of physiological, psychological, physical and musical considerations, finds that probably about 20 oscillations are necessary. His views are confirmed by previous observations of Exner, Von Kries and Toepler.

Mining Share Market.

The market is in a depressed condition, for which there is probable no better reason than that there is no excitement and very little business. If it would be any help to business, we would be pleased to record the finding of bonanzas in all the mines, but, unfortunately, even such reports do not affect the market. There is plenty of money, but it is not being invested in mines. We apprehend that there is a general lull while waiting for the action of the new Legislature. There is some satisfaction in the dull condition of the market, in the certainty that if manipulators are not making sudden fortunes, the majority are not being scalped. Considerable small money is made in the constant fluctuations occurring in a small way. Many purchases in small quantities and sell on a slight advance, satisfied with a few dollars to meet daily expenses. The New York market has boomed and burst also. Soon we may hear reports of the immense number of mines listed there, but the laugh will be on our side when the scalping begins.

A New Mining Code.

We have received from Messrs. Stone & Co., of Denver, Colorado, a copy of M. B. Carpenter's "Mining Code," being a compilation of all the existing mining, water, pre-emption and homestead laws of the U. S., and the State of Colorado, Mining Decisions of the Courts and Department of the Interior, Articles of Incorporation and By-Laws, forms etc., applicable particularly to Colorado. The work is in pamphlet form, printed in excellent type upon good paper. The contents, however, are worthy of special regard. The mining decisions of Judges Field, Elbert, Thatcher and Hallett, in the important cases which have come before them, form a new feature in a work of this kind. The author says that the opinion in the New Discovery—Little Chief case, and the charge to the jury in the Iron—Grand View case, by Judge Hallett, meet the views of geologists, miners and lawyers familiar with the ore deposits at Leadville, and present the law as it will undoubtedly be applied to the mines of that famous camp. A study of these decisions will enable the miner to determine whether he has a vein in place, or a mineral deposit, within the meaning of the mining statutes, as these may be regarded as extreme cases of ore deposits in that district. If the locator has the top or apex of a vein or lode "in place" within the meaning of the term, as construed by Judge Hallett, he may follow the dip of the mineral downward beyond his vertical side lines. If he has not a vein or lode "in place," he will be confined to vertical side lines.

Section 2329, Revised Statutes of the United States, includes all forms of deposit excepting veins in place, under the term "placers." One person can locate 20 acres thereof, unless restricted by local regulations.

As the miner in the carbonate districts cannot usually determine at the outset, whether he has a vein or lode "in place," or a "placer," within the meaning of the act, his safest course is to make a location as upon a lode, for he will then hold all within his surface lines, if it turns out to be a "placer," while if he located as a "placer," and it turned out to be a lode, he would, probably not have a valid location.

Perhaps the theory of this advice is good, but in practice it would give but a small "placer," should there happen to be no lode. Still, all of the indications in those districts may point to veins "in place." We hope to be able to refer again to this mining code of Colorado, which we cordially recommend to our readers as containing valuable information.

MINES IN THE EASTERN MARKET.—While it is certain that foreign capital is seeking investment in the mines of the United States, there is considerable caution exercised by foreign capitalists before purchasing. There are more inquiries than ever made about the value of mines now in the Eastern market. Their number is enormous, Arizona alone being reported to have some 1,700 mines for sale in the New York market. It is becoming the custom among foreigners to secure the services of their various consuls in this country to make inquiries concerning proposed mining ventures. These naturally seek information of the Interior Department at Washington, supposing that the standing and prospects of mining companies will be known there if anywhere. It is a matter of regret, however, that the Department has not always knowledge of the company or the mines it is operating. The reason is, many companies having bogus claims have nothing upon which to base an application, and of course there is no record in the Department. Foreigners naturally believe that when the Government records do not show the existence of a company that the company is a bogus one. Although many excellent claims are put upon the market, yet they cannot be sold through lack of satisfactory recommendations.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

BUTTE BASIN.—*Ledger*, Nov. 29: It is thought probable that a new shaft will have to be put down, or a tunnel constructed to get rid of the immense flow of water which prevents prospecting.

YERFORSK. The sinking operations which were prosecuted in both shafts through the summer are finished. The shaft, which is an incline, now reaches into the earth 950 ft, somewhat more than 800 ft in actual depth. The lowest point from which ore is extracted is the 300 level. The ore is of excellent grade; better, in fact, than has been the average for the last year. The quantity is slight but enough to exclude all idea of the exhaustion of the mine for almost a generation. Opening up a new level at 900 ft is progressing.

RED HILL GRAVEL CLAIM.—W. A. Nevills is running his gravel claim at Red Hill, with encouraging prospects. By means of a pipe over 6,000 ft in length, they are enabled to wash the very crest of the hill, thereby bringing a large extent of virgin ground within the scope of mining operations. All the ground worked in that vicinity in early days proved very rich, and all the indications warrant the belief that the balance of the fill will pan out equally well. One day this week from \$8 to \$10 in coarse gold was picked up on the surface. From 60 to 80 inches of water is all that is required to operate the claim, and the water supply is likely to last till next July.

ZEUS.—At this mine a dozen carpenters are hard at work with the mill. With a couple of weeks of fine weather, the fitting of the framework will be nearly completed. The grading operations are also nearly finished.

LUCKY BALDWIN.—Last week the Superintendent was in Plymouth with some rich ore taken out of the bottom of the shaft, which is down 100 ft. The mill and claim is situated near Big canyon.

NEW QUARTZ MINE.—Figg and Harris have struck a rich quartz mine eight miles northeast of Plymouth, two or three miles this side of the South Fork. Some of the ore, it is believed, will pay \$200 per ton.

REPAIRING FURNACE.—Last week the Empire mining company had a strong force of hands at work repairing the furnace on the big ditch, over the South Fork. The water was turned off some days from the ditch, but the works had a full supply from the South Fork ditch. There is now about 1,000 inches going down the main ditch, and 600 inches in the South Fork ditch.

ENTERPRISE MINE.—The Enterprise mining company have struck the ledge in their tunnel, and are now in the ledge a distance of 14 ft, but have not as yet found the footwall. The character of the ore is said to be good.

PIONEER.—Two samples of rock from the Pioneer, sent below a week ago, assayed well. One lot went as high as \$28 per ton. The description of rock, of course, is not wide. The ore body adjoining, from which the other sample was taken, yielded over \$10 to the ton.

NEW MINE AND MILL.—The old Frank Walker quartz mill, near Enterprise mine, has been taken down and removed to Montezuma hills, about two miles above Nashville, between the North and Middle Fork of the Cosumnes. The quartz ledges in that section are narrow but rich. Twenty years ago the Harvey Bros. had a mill and mine near the present property, but from some cause it has not been worked lately.

BUTTE.

BANNER MINE.—*Oroville Mercury*, Nov. 29: The ore is yielding at the rate of \$50 per ton. The 15-stamp mill completed last week is now in operation crushing about 30 tons of rock per day. The main shaft is already sunk to a depth of 225 ft. In the mine 12 men are engaged in running the main drift on the 200 level and stoping on the ledge; night and day shifts. A six-inch vein of quartz has been struck in the main drift north, which is gradually expanding as the rock progresses. From the mouth of the shaft, the ore is taken 150 yards on a tramway to the dump, from whence it is hauled to the mill by wagons. Sufficient material is on the ground to construct an incline plane tramway to the mill, and the improvement is now being made. A comfortable lodging-house, 24x30 ft, has been built by the company for the accommodation of the employees. Though but recently opened, the mine produces excellent ore. Twenty years ago over \$600,000 were realized from 12,000 tons of ore taken from this mine. A singular coincidence in connection with the practical resume of operations in the mine is found in the fact that Wednesday, which was the first full day's work done by the stamps, was the 20th anniversary of the disastrous cave which caused the property to lie idle since 1859.

INYO.

BIO STRIKE.—*Independent*, Nov. 22: By Wednesday evening's stage, we received a piece of chloride and sulphur lead ore, sent as a fair sample of a new bonanza struck that day in the Indiana, or Boller & Tuttle mine, about 10 miles west of Darwin. This specimen is of about five pounds weight, with one broad, perfectly smooth side, showing contact with an equally smooth clayey wall; its assay value is certainly not less than \$500 to the ton. The important point to be noticed is, that the meager developments already made show that there is a solid width of just that kind of ore full three and one-half ft wide; this is at the 100 level, some 15 ft from the mouth, and about 100 feet from the surface; the tunnel was run all the way on the ledge. This is doubtless the most valuable strike we have had to chronicle for many a day.

OLD COSO.—*Independent*, Nov. 20: We have it upon the authority of Mr. Lasky, merchant of Lone Pine, that the Mexicans have now running in Old Coso 14 arastras, and all of them producing gold. Old Coso is situated about nine miles west of Darwin, and is the oldest mining camp in Inyo county, having been worked as early as '41. It has ever been the resort of Mexicans, and in early days has supplied many a "raise" for some of the toughest citizens that California ever had, more especially when their existence elsewhere was rendered uncomfortable by the authorities. The statistics of the place will never be known. The great ledges are small and flat, but many in number and extremely rich. Aside from a good opening for a small mill to reduce the ores, the accumulation of tailings furnishes a show for a big "specie" by the concentrating process.

BEVERIDGE.

BEVERIDGE DISTRICT.—Besides the works of Messrs. Porter, Hunter & Co., there are in operation at Beveridge district five small arastras working on lead ore, making about nine miles west of Darwin, and the oldest mining camp in Inyo county, having been worked as early as '41. It has ever been the resort of Mexicans, and in early days has supplied many a "raise" for some of the toughest citizens that California ever had, more especially when their existence elsewhere was rendered uncomfortable by the authorities. The statistics of the place will never be known. The great ledges are small and flat, but many in number and extremely rich. Aside from a good opening for a small mill to reduce the ores, the accumulation of tailings furnishes a show for a big "specie" by the concentrating process.

MONO.

BENTON CON.—The *Bodie News*, of Nov. 30th, contains the following account of the Benton Con. The 200 level has been opened from the shaft on two parallel veins, designated the east and west veins. The width of the ore channel can be averaged at five ft, with here and there a horse of porphyry, but which does not affect the general size of the vein, nor detract from its continuity. The 300 level north is 340 ft on west vein and south level 102 ft. On the 400 level south vein has been run a distance of 200 ft, and a rich vein of ore, assaying from \$80 upward, and a drift south 330 ft, also carrying a four-ft vein the entire distance of good milling rock. From the drift south a crosscut has been run east and the east vein encountered at 41 ft, from whence drifts were started on an ore channel four and one-half ft in width, with not a pound of waste rock. At 200 ft south vein was encountered, and a crosscut was run east 64 ft. On the latter vein a crosscut was run west 64 ft and out the main west vein, whence a drift south has been advanced 30 ft, showing two and one-half ft of solid ore. On the east vein, 100 ft further south, a crosscut has been run west 57 ft, which has again cut the

main west vein. A drift south has been run from this latter point, and has now reached a distance of 30 ft, where a winze was sunk, which is now down about 28 ft. Here the vein has increased to a width of over seven ft, carrying float-bucking quartz which will assay well. A drift has been run 195 ft on the 600 level, whence a crosscut was started and run to the east vein, a distance of 68 ft. Here a drift was run south a distance of 63 ft, showing a vein from two to four ft in width. The lowest workings have reached a depth of 700 ft, where water prevents development.

SOUTH NOONDAY.—The main shaft has been sunk in two compartments a distance of 74 ft, and at 70 ft cut through the ledge, which is over three ft in width.

USARVY. Main shaft now down and timbered 250 ft. Work on skip finished, and is now running satisfactorily, with counter-balance and all apparatus connected with it complete. Notwithstanding the delay consequent on putting in this skip, have made a progress of 10 ft during the week. The formation has not changed, still the most obstinate character of porphyry is impeding operations somewhat, still carrying the seams of quartz mentioned in last report. The machinery at the mine and works is working well, and the best progress possible is being made.

MARYLAND CON.—Since last report a distance of 19 ft has been gained from the station at crosscut. When this station is completed, the company will immediately begin to take out ore from the ledges in the north and south drifts at the 253 level of the old incline. Sinking in the main shaft will continue uninterruptedly in the meantime.

NEVADA.

EL CAPITAN.—*Nevada City Transcript*, Nov. 20: The owners of the El Capitán mine, at the head of Gold flat, a mile and a half south of this city, are rapidly getting ready to commence the systematic development of their property. The new hoisting works are about completed, and steam will be started up the early part of next week. The incline, which has been sunk to a depth of 50 ft with windlass, shows a two-ft vein of free-milling ore in the center that contains an encouraging amount of free gold and sulphur. The shaft is 25 ft divided into two compartments, and well timbered with 8x8 inch stuff. A contract has been let for sinking an additional 100 ft on the incline, so as to give it a total depth of 150 ft. The first level will be made at 100 ft, one drift running north and the other south. Three eight-hour shifts are to be kept on, as it is the desire of the company to lose no time in proving their mine. From the El Capitán mine, the New York Gold mining company, and represents Eastern capital altogether, owns the El Capitán, which contains 1,000 ft, the southern extension known as the Clinton and embracing 1,500 ft; also the northern extension for 1,000 ft, called the Wheel Jane. The Crosby and Olive claim of 2,100 ft intervenes between the Wheel Jane and the eastern extension of the Providence Gold and Silver mining company's property. The President of the company, Mr. E. G. Bloss, of New York, is now in this city, and will remain till the works are in operation.

MERRIMAC CLAIM.—The tunnel in the Merrimac prospecting gravel claim, situated next to the Round Mountain mine, is now in 350 ft. Some good prospects are being obtained, and it is thought the pay channel will be developed within a reasonable time. This property is owned by some of the best practical miners in the country.

NORWICH MINE.—*Grass Valley Union*, Nov. 30: This is a quartz location on the east bank of Wolf creek. For several months the owners have been sinking a perpendicular shaft, through hard ground, to strike the ledge, and during the present week, at the depth of about 65 ft, the shaft opened on a 10-inch ledge, which shows finely in free gold and silver. The point at which the ledge was struck is 30 ft below the level of Wolf creek.

BULLDOZER.—*Transcript*, Nov. 27: Two drifts were started Tuesday in the Bulldozer mine, on Deer creek, at a depth of 30 ft. Some promising looking ore is being taken from the ledge, which is from 12 to 18 inches thick. The incline has been pushed down 50 ft. Sinking has been temporarily suspended, but will be recommenced as soon as a good sized crushing mill can be taken out.

CENTENNIAL.—A crushing of 30 loads of Centennial rock is now going on at the Orleans mill. It is estimated to go \$80 per load. The rock now coming out of the mine is of equally good quality.

NEW YORK HILL.—The incline shaft of the New York Hill mine is down 70 ft below No. 10 level, or a total depth of about 1,120 ft. At the depth of 100 ft below No. 10 a new level will be started, which will be commenced about the 1st of January, as sinking is progressing at the rate of eight ft per week.

PEAVINE ORE.—*Truckee Republican*, Nov. 26: Leo Butts has erected a miniature furnace and smelting works in the rear of James B. Giffen's residence, and has been engaged for some days in testing Peavine ore. His results are extremely satisfactory, and he claims that he can work the ore readily and profitably. His method of working is a modification of the Gould process, and is known only to himself. Mr. Butts has been at Meadow Lake throughout the recent tests of that ore, and has had an important share in the honor of reducing these hitherto rebellious ores. Preparations will soon be made for working Peavine ore on a large scale.

WOOD'S RAVINE.—*Transcript*, Nov. 26: Wood's ravine, near Nevada City, has developed into one of the best quartz mining sections in the county. Prospecting is now going on to discover an old shaft which, in 1850, was abandoned, because it was thought impossible to extract the gold from the rock.

PHOENIX MINE.—*Herald*, Dec. 2: Work has been commenced on the Phoenix, formerly called the Cunningham mine, situated about 10 miles west of Nevada City, where the main shaft about 210 ft below the surface. The tunnel is about 1,000 ft long. This mine has paid handsomely, and why it was closed down is unknown.

PLACER.

OPHIR TREAS.—*Apex*, Nov. 20: Bowon, Hillman & Co., of the Utah Salt claim, John Woodard's ranch, about a mile southwest of Ophir, are crushing some very fine rock this week. They have over sixty tons of it, and it will pay probably as high as \$35 a ton, if not more. Trembling Bros. are also taking out some excellent rock from their mine at Humboldt Flat, on the old Bellevue lead. Their last crushing averaged over \$60 per ton, and the quartz they are getting is still richer.

DRUM FLAT. The *Fortuna* star: The first blast of the season was fired at the Polar Star claim a few days ago. It was an entire success, loosening up a large quantity of dirt. The drift was in 50 ft, and contained 3,250 pounds of Judson powder. Washing will commence as soon as a sufficient supply of water can be obtained. Only two mining claims have done anything at washing yet—one of these belonging to the Bodine mine, owned by Mr. J. H. Leckman. Several others are fitting up, hoping for early rain and snows. A good mining season is pretty generally expected.

BIO RIVER STRIKE.—*Herald*, Nov. 29: Some time ago we referred to a strike having been made by R. Boles, near Rutlesnako Bar, on the American River. We learn that John McElroy, of the Bodine mine, has the claim with him. Several others are fitting up, hoping for early rain and snows. A good mining season is pretty generally expected.

SIERRA.

REU RICH.—*Bodie News*, Nov. 30: Some marvelously rich ore was recently struck in the Ketoon mine at Alleghany, Sierra county, California, and 1,000 pounds of it has been taken to Nevada City for reduction. It is very heavy in arsenical pyrites, but shows no free gold. Assays made show that it contains over \$21,000 worth of gold per ton.

DOWNVILLE.—*Downville Messenger*, Nov. 29: The Secretary of this company, Platt Ketchum, informs us that his men are driving off northeast and entering some very fair gravel that prospects about two dollars to the car, with heavier wash and larger boulders than heretofore. The main tunnel is being put in good shape for

water operations. Seventy-five car-loads of pay dirt is thrown into the dump every day.

NEVADA.

WASHOE DISTRICT.

OPHIR.—*Gold Hill News*, Dec. 3: During the past week the main incline has been sunk and timbered 15 ft, and is now 171 ft, on the slope, below the 2400 station, passing through very favorable vein matter containing quartz giving low assays.

UNION CON.—On the 2400 level the east drift has been advanced 20 ft, making a total length of 54 ft in ore, and still showing high-grade ore in the face. They are now extracting ore from this level at the rate of 100 tons per day, which quantity will be increased as the bob and tank pits in the Union shaft are completed. The total amount of ore extracted to date is 1,182 tons, of which 337 tons have been shipped to the mill, leaving 845 tons in the ore house.

SERRA NEVADA.—North drift on 2500 level is now in a distance of 94 ft from the station, the face showing a very favorable formation of clay, porphyry and quartz, giving low assays. The face of this drift is about 650 ft north of the incline. The ore stops on this level are yielding 35 tons per day of good ore. They did not take out more, if they had the facilities for handling it. On the 2500 level the north drift is now in a distance of 36 ft. At this point a drift has been started east for the purpose of proving the vein in that direction. The west crosscut on this level is in a distance from the station of 70 ft. A drift has been started north on the ore vein, which is now in a distance of 18 ft, the face showing ore in fair grade.

CALIFORNIA.—East crosscut, from main drift, is now in 20 ft, and shows favorable-looking vein matter in the face. On the 2500 level the north drift from the C & S shaft has been extended 33 ft; total length, 118 ft. It has not yet reached the ore vein found on the 2150 level.

SAGE.—During the past week the crosscuts on the 2200 level have been advanced. No. 1, 33 ft, total 132 ft; and No. 2, 24 ft, total 102 ft. In crosscut No. 1 they have passed through 48 ft low-grade quartz, and in crosscut No. 2, 72 ft, and the face still in quartz. The south winze, 2200 level, has been retimbered 20 ft. The tank drift, 2200 level, has been advanced 13 ft; total, 40 ft. The water stands about 15 ft below the 2200 level.

BLAKE & NORTON.—Work on the 2100 level has been temporarily suspended. On the 2200 level crosscut No. 2 is in 50 ft, showing occasional seams of ore. The south drift has been cleaned out 123 ft. The Savage company stopped sending water to the pump of this mine last night, reducing the temperature to 28 degrees Fahrenheit, which will greatly facilitate work on this level.

MEXICAN.—On the 2000 level the Joint Union Con. west crosscut on their north line has been advanced 30 ft through vein porphyry and clay streaks, total length of 210 ft. The main drift, 320 ft. The Joint Union Con. winze has been sunk and timbered 14 ft, and is now 204 ft in depth below the 2000 level, continuing in a vein matter showing some water.

MOUNT ROSE DISTRICT.

MOUNT ROSE.—*Silver State*, Dec. 2: The Mount Rose, under the management of Capt. Rawlings, is proving to be one of the best mines in Mount Rose district. The ledge is large, rich and well defined at the greatest depth attained.

THE FAIR.—This mine is improving. Two shifts are at work on the vein, which has been found beyond the break. The ledge is not so rich as was near the surface, but its appearance indicates that it will be, ore long, as large and rich as it ever was.

COMO DISTRICT.

MARY WILDER.—This mine, six miles west of Paradise village, continues rich as far as prospected. A shaft is down about 12 ft on the ledge, and at that depth there is a streak of ore about a foot wide that assays from \$300 to \$1,200 per ton.

HOT CREEK DISTRICT.

RICH FIRE.—The new mines discovered last week, near the Hot Springs mine, 12 miles east of Paradise village, are said to be very extensive. There are immense masses of quartz on the surface, some of which assay \$800 to the ton in gold and silver.

BELMONT DISTRICT.

BELMONT.—*Courier's* last report says: Since last writing you we have commenced stoping in north part of mine on the largest body of ore opened up in mine for several years. The body of ore is about 200 ft long. We have cut through with Nos. 2 and 3 raises and found it over forty feet wide in both. Our ore body north of shaft is also looking fine and producing rich ore. We are extracting now some 40 tons of ore per week, and as soon as we get the necessary repairs made on mill, which will take us until the 25th of present month, we will put on a larger force of miners and take the work the more readily and profitably. His method of working is a modification of the Gould process, and is known only to himself. Mr. Butts has been at Meadow Lake throughout the recent tests of that ore, and has had an important share in the honor of reducing these hitherto rebellious ores. Preparations will soon be made for working Peavine ore on a large scale.

WOOD'S RAVINE.—*Transcript*, Nov. 26: Wood's ravine, near Nevada City, has developed into one of the best quartz mining sections in the county. Prospecting is now going on to discover an old shaft which, in 1850, was abandoned, because it was thought impossible to extract the gold from the rock.

PHOENIX MINE.—*Herald*, Dec. 2: Work has been commenced on the Phoenix, formerly called the Cunningham mine, situated about 10 miles west of Nevada City, where the main shaft about 210 ft below the surface. The tunnel is about 1,000 ft long. This mine has paid handsomely, and why it was closed down is unknown.

</

Quinn Mine, Lyon County, Nevada.

A late *Territorial Enterprise* gives an account of the Quinn mine, in the above county, which contains rich silver ore, and which is now about to be properly opened. The history of the mine is substantially as follows:

Nearly 20 years ago, Patrick Quinn discovered and located a lode in Spring valley, below Silver City, which was found to be very rich in silver at the very surface—in the grass-roots, as one may say. At the time there was much talk and good deal of excitement in regard to the find, for silver ore was something new in that region, all the veins being gold bearing, but as Mr. Quinn was not able to open out his mine on a large scale, and tenaciously held on to it and worked it in his own way, other excitements withdrew the public gaze and Mr. Quinn and his mine were soon forgotten, or only remembered by the few who formed his little world.

As we have said, Mr. Quinn has worked the mine all these years in his own way, and his way was much after the fashion of Mexican mine owners. He has a comfortable house near the mine, and there he has lived and supported his family, digging the ore from his mine by trenching along on the surface and grinding it in an arrastra, or sometimes getting some acquaintances to work small lots of it in a pan, he screening out the fine dirt for this purpose.

A year or so ago Col. F. F. Osbiston and Dr. Bronson obtained a controlling interest in the mine and intended opening it up at once in good shape, but the Sierra Nevada, Leadville and other excitements diverted their attention from time to time, and besides they did not then know the real value of the mine.

All this time, however, Mr. Quinn (although the control had really passed from his hands) was digging away at the mine more or less, as he was bound to get a living out of it, and had laid bare the ore in a number of places. At odd times Mr. Quinn put in considerable work on a shaft, and from this has taken out a considerable amount of ore, as it was sunk on the vein. This shaft finally attained the depth of 80 feet, when water was encountered, and Mr. Quinn was at the end of his string, for he could make no heading with an ordinary bucket and windlass, when he had to take out 10 buckets of water to one of ore, which at last came to be the case.

The vein has widened from three to four feet at the surface to twelve feet at the bottom of the shaft. From the very surface it has well-defined foot and hanging walls and the regular Comstock pitch to the east. The hanging wall is very handsomely shown in a tunnel that runs under the main road leading to Carson. It is very regular and as smooth as though it had been plastered. In an open cut to the southward the footwall is shown, and it is well defined and almost vertical. Next to this wall, from the very surface down, is to be obtained fine milling ore.

Dr. Bronson is now sinking a new shaft to the northward of the old one and to the eastward of the vein. This shaft is of two compartments of the usual size and is neatly and substantially timbered. It is the first work that has ever been done on the mine in anything like shipshape. The shaft was started on the first of the present month, and has attained a depth of 65 feet. It will be sunk to the depth of 100 feet, when a crosscut will be run west into the ledge, though we are of the opinion that the ledge will so widen that the shaft will cut through the hanging wall at this depth mentioned. In the bottom of this shaft is a feeder over a foot in width, which is making west and which is metal bearing, assaying from \$3 to \$5.

The ore does not look at all like the ores at this end of the Comstock. It varies in color from a dull yellow to a rusty red, and looks like material wholly gold bearing, yet silver largely predominates in even the reddest of it.

In the old Mexican mine, about the 300 level, were found streaks of this yellow-looking ore, and in it, as in this of the Quinn mine, small flakes of native silver were frequently found.

Samples were carefully assayed by Wiegand & Co., and the following are the results: No. 1, \$35.17 gold, \$66 silver; total, \$101.17. This was the average of a large pile of ore taken out of the 80-foot shaft, the bottom of which is now filled with water. The sample was taken from a dozen places on all sides of the dump.

No. 2, \$79.94 gold, \$14.40 silver; total, \$94.34. This was from the bottom of an open cut six or eight feet in depth, and on the flat ground a considerable distance south of the shafts.

No. 3, \$33.58 gold, \$493.80 silver; total, \$527.38. This was a piece of very hard quartz of a grayish hue with a considerable tinge of green in seams, and with small specks of black peppered over it. While hammering at it to break it and get a pocketable piece, we were assured by both Dr. Bronson and Mr. Quinn that it was of little value. They said it was altogether too hard and flinty.

Not satisfied with our own assays we obtained several of the samples taken by parties who visited the mine a few days ago.

A sample from the dump mentioned above, taken by Samuel L. Jones, Superintendent of the Crown Point, showed \$62.83 silver and \$32.64 gold; total, \$95.47.

A selected piece taken by Mr. Jones went \$392.60 silver and \$52.23 gold; total, \$444.83. A sample from the waste dump assayed \$20.

His sample from the open cut went \$82.20 silver and \$18.40 gold; total, \$100.60.

Mark Strouss had an assay made of a sample from a drift in the old shaft (covered with water at the time of our visit) which gave \$43.60 silver and \$20.78 gold, or a total of \$64.38. Mr. Augustine, from the waste dump, \$21.19 silver and \$12.55 gold, or a total of \$33.74.

James R. Field, from the dump, \$190.10 silver, \$66.15 gold; total, \$256.25. H. Crandall, specimen from dump, \$626.95 silver, \$159.08 gold; total, \$785.43. Mr. Gowan, of San Francisco, from dump, \$137.53 silver, \$47.57 gold; total, \$185.10; from waste dump, \$47.

From these samples it will be seen that the Quinn mine is not only remarkably rich, but also very rich in silver. At depth it will undoubtedly be found to contain a large bonanza. It is evident that a large and rich ore chimney has at this point pushed its way to the surface. As evidence of this we would call the attention of mining men to the huge mass of vein matter that has been pushed high above the surrounding surface at a point about 100 feet north of where the new shaft is going down. This rugged mound of vein matter forms a noticeable feature of the landscape, and ever since the settlement of the country must have been observed and remarked upon by all traveling that way between this city and Carson.

The Quinn mine will be found to be on the true line of the Comstock. Its course northward is first to the mine where stands the old mill built by Gen. Thomas H. Williams on a mine worked by him, the precious metals found in which now repose in his tailings' dump; thence to the Kossuth, Dayton, Succor, Forman shaft and Yellow Jacket new shaft. From the bill north of the Quinn the works of all these companies will be found to be in a direct line north and south.

Presence of Mind.

A singular accident, attended with a remarkable display of presence of mind, occurred a short time ago at Dr. Buelow's quartz mine five miles east of Nevada City, California, which is thus spoken of by the *Transcript*: G. H. Kirchhacker, a middle-aged man, had put in a blast at the bottom of the shaft, which is 80 feet deep, and then after lighting the fuse gave the men at the windlass the signal to "hoist away." When the bucket he stood in had been hoisted to a point about 30 feet from the surface, a splice in the rope gave way, and Kirchhacker was precipitated a distance of 50 feet straight down into the lower depths. Strangely enough the force of the fall did not render him insensible, although he was stunned for an instant. One ankle was dislocated, a knee-pan hurt, neck cut and other slighter injuries received.

Almost as soon as his downward course was checked, he realized the fact that but a few seconds would elapse before the explosion of the blast, and his consequent annihilation, unless he took immediate measures to save himself. He managed to draw his mangled body over to where the fire was creeping down to the heavy charge of powder beneath. No time was to be lost. Grasping the burning fuse, he summoned up his remaining strength, and drew it out from the tamping.

His companions on the surface were in an agonizing state of suspense for a few minutes. When several moments had elapsed and no explosion followed, they started down for the purpose of getting the remains of the victim, whom they supposed had been dashed to pieces. Their surprise and joy was unbounded at finding him alive. He was hauled up, and Dr. Buelow at once sent for. So far as yet ascertained he received no internal injuries, and will be as well as ever again in a few days.

DARIUS' TOMB.—Among the most remarkable tombs of the ancients may be noticed the sepulcher carved out of the living rock by order of Darius, the warrior and conqueror King of Persia, for the reception of his own remains, and which is existing to this day at Persepolis, after a duration of 23 centuries. The portico is supported by four columns 20 feet in height, and in the center is the form of a doorway, seemingly the entrance to the interior, but it is solid; the entablature is of chaste design. Above the portico there is what may be termed an ark, supported by two rows of figures about the size of life, bearing it on their uplifted hands, and at each a griffin—an ornament which is very frequent at Persepolis. On this stage stands the king, with a bent bow in his hand, worshipping the sun, whose image is seen above the altar that stands before him, while above his head hovers his ferocious or disembodied spirit. This is the good genius that in Persian and Ninevite sculpture accompanies the king when performing an important act. On each side the ark are nine niches, each containing a statue in bas-relief. No other portion of the tomb was intended to be seen, excepting the sculptured front; and we must, therefore, conclude that the entrances were kept secret, and that the avenues were by subterranean passages so constructed that none but the privileged could find their way. We are told by Theophrastus that Darius was buried in a casket of Egyptian alabaster, and also that the early Persians buried their dead entire, preserving their bodies with honey or wax.

Ancient America.

Dr. J. M. Peebles, in a recent lecture in San Francisco upon the above subject, took occasion to say that his face once crimsoned in Egypt when asked by a scholarly native engaged in the Cairo Museum how the buried and half-buried cities of Central America and the pyramidal ruins of Yucatan and southern Mexico compared with those of Egypt. The lesson was: "Visit and study the wonders of your own country before traversing foreign lands." This speaker pronounced the railroad from Vera Cruz to the City of Mexico a splendid specimen of engineering. The Aztec Anahuac, the vale of the Montezumas, has an area of some 600 square miles. It was the sunny home of the old Aztecs. The Aztec and Toltec relics preserved in the City Museum of Mexico were intensely interesting, inasmuch as they established the fact of maritime relations and inter-oceanic intercourse between the Toltecs and the Phenicians and Egyptians. As the Lamentian rocks, far to the north of us, constitute the oldest range of rocks in the world; as Cholula is considered the oldest pyramidal structure known, why may it not be true that this is the old world, and that the Egyptians learned pyramid-building from the ancient Americans of this continent? "I saw," said the speaker, "carved upon temple ruins in Yucatan, hawks' and other birds' heads similar to those upon the temples, tombs and obelisks of Egypt. Among the ruins of Uxmal and Palenque I saw the carved cross and the same phallic symbols so common in India, Phœnicia and the East; and I further saw the chiseled serpent, the mummy-shaped sarcophagus, the winged rod and the lamp immortal, so frequently seen in Egyptian tombs and temples. Few men of research doubt the existence and sinking of the Atlantis Isle; doubt that there were commercial relations in ancient times between this country, Toltecs probably, and the old nations of Europe and Asia. Strabo, living before Christ, said 'that the art of night-sailing was taught in ancient Tyre.' This indicates a knowledge of the mariners' compass. Possibly the second expedition sent out by Necho II, an ancient Egyptian king, reached this continent. The first expedition of this king sailed down the Indian ocean, doubled the Cape, and entered the Pillars of Hercules. The ancients in some respects equaled if not excelled us. The Aztecs conquered the Toltecs and then adopted more or less of their arts and sciences. The calendar stone that now rests against the side of the Roman Catholic Cathedral in the City of Mexico is a Toltec rather than an Aztec production. Is it asked, 'Who were the Toltecs?' They were the descendants of the Nahuas, and this was a conglomerate nationality, made up of the autochthonic races and the remnants of those who peopled the Atlantis Isle. Traveling in Yucatan is hardly safe and very inconvenient. Merida, the capital, has but one hotel, and that is kept by a Spaniard. It is 65 miles from Merida out to Uxmal. The Maya Indians in these regions are friendly, but the southern tribes are warlike."

Globe District, Arizona.

The speedy completion of the Southern Pacific railroad and its connections, will furnish what is most needed to properly develop the wealth of Arizona, viz: transportation. The great hardships and deprivations that have been suffered by the pioneers in that mining Territory deserve some recompense for their stout-hearted perseverance. The mines are looming up, and if all of the districts are as flattering as Globe district, there need not be any fears of ultimate success. Mr. F. A. Wilder, writing to the *Silver Belt* of Nov. 22d, says: We have seen ore that was taken from the Stonewall Jackson shaft at a depth of 300 feet, which is estimated will assay \$10,000 per ton; have also seen a specimen of native silver from same mine, purer than the current coin of the realm, which confirms Wordsworth's statement, that "true hearty dwells in deep retreats." These specimens can be seen in Eaton & Bailey's cabinet.

The Duryea mill has contracted with Moore & Trout for 500 tons of Chrome ore. One hundred tons are already on the dump. It looks well. The mill is being re-fitted with new machinery, a crusher, an automatic feeder, two additional pans and settlers. A new mill building is being erected. The capacity of the mill when completed will be 12 tons. It will be in operation in about six weeks.

In regard to the Silver Nugget, Mr. W. estimates the shaft at 50 feet in depth. The past week a new crosscut was started from the west drift, northerly, has advanced some eight feet, developing, at this point, a vertical vein; its direction, or strike, being nearly east and west. The gangue is granular quartz, containing disseminated crystals of feldspar mineralized with chloride, sulphide and arsenate of silver. The latter not purely a ruby stained ore, but allied to it so nearly that it may be said to approximate such. I do not know the assay value of this ore, but from its appearance to-day, presumes it will pay largely to mill. The indications of the vein promise a strong one.

Also the East Richmond is a valuable mine. It is upon the main vein of the Richmond proper, adjoining the Mack Morris, westerly. The vein has been traced from the eastward of the La Plata, or old McDowell claim, through it, the Mack Morris, and the entire Richmond locations, thus constituting, I think, the center

lines of the several claims, with 300 feet on each side, as this width thereof. The size of this vein, as indicated at the surface, is over 12 feet, and its outcrop is seen at intervals along the entire line, as mentioned above. To the northward its enclosing wall or country rock is syenite and syenite gneiss. To the southward the country rock is porphyritic granite. At the center of the ground, distant about 700 feet westerly from the Mack Morris, a working shaft has been sunk to the depth of nearly 50 feet, its south line following, as is supposed, the foot-wall of the vein. From surface to bottom of shaft ore has been taken. At 25 feet a drift eastward, following the strike of the vein, is now being run, seven feet in width and six and one-half feet in height, and at this date 18 feet in length. Every part of this drift is in ore, its floor, roof, sides and face yielding a gangue strongly mineralized with chlorides, sulphides and arsenate of silver, diffused with much uniformity. The present appearance of the vein gives promise of a large quantity of ore. Appended is the result of eight assays from the vein gangue, taken from different parts, only one being a selected specimen. Assays of ore average \$1,245.54.

Astronomical Causes for Rainy or Cold Summers.

In reply to an inquiry, one of our Eastern exchanges expresses its common-sense views upon the above subject: There can be no astronomical causes for rainy or cold summers, for the simple reason that they do not extend over the whole earth, but are merely local. If there were an astronomical cause, the effect would be general over the whole earth; but what do we actually find? Take the most recent peculiarities of the weather—while we in the United States had very dry and warm weather in October, there was in Spain an overabundance of rain and very destructive floods, by which millions of dollars' worth of property was destroyed and hundreds of persons perished, while in Austria it was very cold, and Vienna was afflicted with snowstorms.

A few years ago, when we had a very cold and wet summer, and some of our would-be scientists were discussing the great number of sun spots as a cause, we called attention to the fact that, according to reports from Europe, the weather there was very hot and crops suffering from want of rain. We hold that the total amount of evaporation and rainfall averaging over the whole surface of the earth is very nearly a constant quantity, and sun spots do not diminish solar radiation; and if they did, they would diminish this evaporation, and consequently the rainfall, instead of increasing it, because all the water that descends must have first ascended by solar heat, and what has been taken up will come down somewhere. If now, by a series of circumstances, some part of the earth's surface gets more than its usual share at the expense of another part, people commence at once to reason about astronomical causes, without first investigating whether the whole earth suffers in the same way. There is an important fact which proves that if much rain falls in one region it must be carried there from other regions where the weather is clear, and an amount of evaporation takes place adequate to supply that excessive rain; this fact is that if the total amount of watery vapor which the atmosphere can hold were to descend at once over the whole terrestrial surface, it would only amount to four inches, and raise the surface of the ocean as much, but as one-fourth is land, from which it would flow to the ocean, it would cause the ocean to raise its level about five inches.

FLEXIBLE SANDSTONE.—A few days ago Mr. C. A. Hege, of Salem, North Carolina, exhibited to us a specimen of sandstone from that State, which possesses remarkable properties. A whole mountain in Forsyth county is composed of this stone. It is found in strata ranging from one-fourth to three-fourths of an inch in thickness, and is of fine grain and light gray color. The most singular feature is its flexibility. The specimen shown us was ten inches long, one-fourth of an inch thick, and nearly one and a half inches in width. It could easily be bent, and did not appear to be at all brittle. The application to it an emery wheel affects it but little. It is perfectly fire-proof, and will serve an important part in the industrial arts as lining for furnaces, grates, etc., owing to its adaptability to conform to round surfaces, or to the shape of the grates. The existence of this bed of sandstone has been known only a short time. An old hermit living at the foot of this mountain discovered it years ago, and produced specimens as a curiosity. The inhabitants, suspecting that he found the rock in this form, followed him and discovered the secret. Near the surface of the ground the rock is very hard, but farther down it can be easily removed, and becomes very flexible.—*American Inventor.*

EXPLOSION OF FIRE ARMS.—Fire arms frequently burst when the muzzle has been accidentally closed with earth, snow, etc. Prof. Forbes' explanation of this fact is very simple. If the charge moved slowly, a very slight pressure of the air in the barrel would be sufficient to clear the muzzle, but as the charge actually travels with a speed greater than the velocity of sound, the resistance offered by the obstacle becomes excessive and the gun bursts. It has been demonstrated mathematically that the pressure generated by a plug of the density of air is seven and a half tons.

THE ENGINEER.

An Important Engineering Scheme.

While our exchanges are full of the international project of connecting the waters of the Atlantic and Pacific oceans by means of a canal, a scheme is on the cards for effectually draining and reclaiming the fertile marsh lands of Yolo, Solano and Sacramento counties by means of a canal fifty miles long, which will also control the Sacramento river during floods.

Col. Smith, Chief Engineer of the Harbor Commission, and also engineer of the Sacramento River Drainage District, to which he was appointed by an act of the last Legislature, approved April 1st, 1878, is at work upon his report to the latter Board, which was established for the purpose of draining the surplus waters of the Sacramento river and the waters flowing from the east side of the Coast range of mountains, in the counties of Yolo and Solano, into Suisun bay—an object to be effected by the construction of a main canal, leading from the Sacramento river at Charleston, or Gray's bend, in the vicinity of Knight's Landing, Yolo county, running in a southerly and southwesterly direction to the basin of Nurse's slough, in Solano county, and thence to Suisun bay, through Montezuma slough, an entire length of about 50 miles, and at a distance of from five to ten miles northwest of the Sacramento.

The waters from the Coast range of mountains from Cache creek southerly are to be diverted and turned into the canal; and an auxiliary canal, leading from the Sacramento, near the mouth of the American river, to the main canal, is to be constructed if necessary. The Commissioners appointed are, Mr. Egbert, of Oakland, and Messrs. Cary and Kuox, of Sacramento. According to the terms of the act, the engineer must make a preliminary survey and reconnaissance for the purpose of ascertaining the feasibility and effectiveness of the proposed work, and its probable cost, and make a full report to the Board. An appropriation of \$10,000 was made for the purpose of paying the expenses incidental to this survey. The estimated cost of the undertaking is placed at \$2,000,000, or an assessment of not more than \$5 an acre on the total amount of lands to be benefited in the district, which is roughly estimated at about 400,000 acres. In the event of a favorable report, bonds for the amount are to be issued, payable in 20 years and bearing 7% interest per annum, payable semi-annually. Col. Smith has devoted much time to the consideration of the scheme, and has consulted every authority of note upon the subject of rivers, which is found to be one of the most difficult that engineers are called upon to wrestle with.

Whatever may be the difficulties they will undoubtedly be overcome. The skill of our engineers has never been at a loss to accomplish calculated results. As one of our daily exchanges says, however, the feasibility of constructing a canal large enough to receive all the superfluous waters of the Sacramento during flood seasons, and also the waters from the Coast range through Putah and Cache creeks, is a consideration that will tax the mind of the best engineers for solution, especially when it is borne in mind that the only available data at all reliable are observations of the State Engineer, which extend over a period of little more than a year. This difficulty once overcome and the greater portions of Yolo, Solano and Sacramento counties will be effectually reclaimed and enhanced in value many millions of dollars.

The main canal will be above the level of the surrounding country nearly its entire length, and must be built securely enough to hold all the waters of the district without danger of overflow or breakage, which would inundate the land and reduce it to its former condition, thereby rendering the entire project a failure. The bed of the canal will be on a level with high water at the point of junction with the Sacramento, so that when the river rises the water will rush into the canal. On reaching the Montezuma hills, a cut will be made through them nearly four miles long. Thence, the canal will extend to Montezuma slough, through which it will flow to Suisun bay. It is improbable that any injury will result to the land in the vicinity of Montezuma slough, because it is at present subject to tidal overflow. On the contrary, it is quite probable that the velocity of the waters flowing through the canal will be so great, that when they enter the slough they will broaden and deepen it, thus affording better facilities for draining Grizzly island, preparatory to building levees for protection against the tides. The matter of damage to the land in the vicinity of the mouth of the canal is a point to which the engineer's attention is especially directed by the Act.

Col. Smith is very reticent about divulging anything relative to the decision arrived at in his report, until he shall have forwarded it to the Commissioners. Nevertheless, it is quite likely that he will report favorably upon the scheme, notwithstanding the gigantic obstacles in the way. Upon due consideration, they do not appear to be absolutely insurmountable. Should he declare in favor of any radical modifications, the project would be abandoned by the Commissioners without submitting it to the people, as the act requires in the event of a favorable report.

USEFUL INFORMATION.

A New Compound for Making Casts, Molds, Etc.

Our exchanges bring us an account of a new cement known as Jaumin's cement, from the name of the patentee, a resident of Paris. The cement is simply a mixture, in suitable proportions, of yellow oxide of lead (the quality known as massicot being preferable) with glycerine. Several other metallic oxides and matters may be mixed with the cement, so as to suit the quality or the color of the cement to the nature of the work to be produced, but the two essential compounds are yellow oxide of lead and glycerine, varying according to the consistency of the cement it is desired to produce. The proportion of glycerine is larger for a very soft cement than for a stiff cement. The exact proportion of each of the two essential compounds are not specified. The paper from which we make our extract says that this cement is specially adapted for molding those objects which require an extreme delicacy in the lines of the cast, such as engraved blocks and plates, forms of printing type, photoglyphic plates, etc. Under the influence of gentle heat it sets in a few minutes, and then resists perfectly both pressure and heat. When set, it is also a very good substitute for natural lithographic stones, and it can replace them for many practical purposes. It can also be used for artistic reproductions, such as *fac similes* of terra cotta, whose color and sonorous quality it possesses. Though setting to great hardness in a few minutes, it does not shrink. Massicot, it may be observed, is an old name for litharge, but the term is more generally applied to the yellow oxide of lead, prepared from the scum of the molten metal by roasting until the color is fully developed.

A mixture of litharge and glycerine forms a well-known cement, discovered, if we are not mistaken, some 10 or 12 years ago in this country by Dr. P. H. Van der Weyde. As a plastic material, however, it is a novelty. We doubt very much whether as a substitute for lithographic stones it will come into use. It is strong and hard and sets rapidly. Some attention must be given to the quality of the glycerine, which must be nearly pure, at least, to form a good cement, capable of setting quickly; it must be free from water and quite thick. We suppose the thick purified article to be found in the drug stores would answer. It is possible that the quality known as crude would answer just as well except for the presence of water. The discovery of the value of this compound as a cement was rather a matter of accident. Dr. Van der Weyde wished to seal a glass stopper into a bottle, so that it would remain perfectly tight, and yet be easily removed when desired. Not wishing to use wax, the material commonly employed for the purpose, he took some litharge, and, mixing it with glycerine, applied it around the stopper. It answered one portion of the requirements of the case perfectly, and the contents of the bottle were kept from leaking, but the doctor found, when he came to empty the bottle, that bottle and stopper were as firmly united as though they had been made in one piece, so that it became necessary to break the neck of the bottle to get at the contents. It is needless to say that it was not again used for that purpose.—*Iron Age*.

The Gelatine Copying Process.

The following is a simple description of the new gelatine process: Write with a steel pen on ordinary writing paper; allow to dry; press the writing gently upon the tablet, allow it to remain a minute, when the greater part of the ink will have been transferred to the gelatinous surface, and as soon as the paper has been removed the tablet is ready to take impressions from. Place ordinary writing paper upon the charged tablet, smoothing over with the hand, and immediately remove the sheet, which will be found to bear a correct copy of the original writing; repeat with other sheets until the transferred ink becomes exhausted. Immediately after, wash the tablet with water and a sponge, let it dry and it is ready again for use. With a tablet and ink prepared according to the following, 50 good copies from one transfer have been obtained, and doubtless with care it would afford twice this number. The proportions for the pad or tablet are: Gelatine, one ounce, glycerine, six and one-quarter fluid ounces. Cooper's gelatine and pure concentrated glycerine answer very well. Soak the gelatine over night in cold water, and in the morning pour off the water and add the swelled gelatine to the glycerine heated to about 200° Fahrenheit over a salt-water bath. Continue the heating for several hours to expel as much of the water as possible, then pour the clear solution into a shallow pan or on a piece of cardboard placed on a level table and having its edge turned up about one-eighth of an inch all round to retain the mixture, and let it remain for six hours or more, protected from dust. Rub over the surface a sponge slightly moistened with water, and let it nearly dry before making the first transfer. The ink is prepared by dissolving one ounce of aniline violet or blue (2 R B to 3 B) in seven fluid ounces of hot water, and, on cooling, adding one ounce of wine spirit with one-quarter ounce of glycerine, a few drops of ether and a drop of carboic acid. Keep the ink in a well-stoppered bottle,

CHINESE METHOD OF WELDING CAST-IRON.—The Chinese process of welding cracked iron wares by cementing them with molten iron is thus described: In the case, for example, of a cast-iron pan requiring such treatment, the operator commences by breaking the edges of the fracture slightly with a hammer, so as to enlarge the fissures, after which the fractured parts are placed and held in their natural positions by means of wooden braces; the pan being ready, crucibles made of clay are laid in charcoal and ignited in a small portable sheet-iron furnace, with bellows working horizontally. As soon as the pieces of cast-iron with which the crucibles were charged are fused, it is poured on a layer of partly charred husk of rough rice previously spread on a thickly doubled cloth, the object of this being to prevent the sudden cooling and hardening of the liquid metal. While in the liquid state it is quickly conveyed to the fractured part under the vessel and forced with a jerk into the enlarged fissures, while a paper rubber is passed over the obtruding liquid inside of the vessel, making a neat, strong, substantial, and in every respect thorough operation.

BLEACHING FEATHERS.—A new method is said to have been devised for bleaching feathers, which, it is thought, will supersede those methods now and previously resorted to. This improved practice rests on the interesting fact that feathers immersed in resinous essences—such as turpentine and other hydro-carburetted oils from distillation of resinous juices in general, or in like oils, in lavender, thyme, etc., or in bituminous hydro-carbons—are discolored under the action of light and heat. The feathers, especially ostrich plumes, are kept in the vessels a longer or a shorter time, according to the degree of bleaching intended, at about 86° Fah., while exposed to light as much as possible. In three or four weeks they are dried and prepared according to known methods.

TO SOFTEN PUTTY.—Slack three pounds of stone quicklime in water, then add one pound of pearlash, and make the whole about the consistency of paint. Apply it to both sides of the glass and let it remain for twelve hours, when the putty will be so softened that the glass may be easily taken out of the frame.

GOOD HEALTH.

How not to Take Cold.

Dr. Beverly Robinson, discoursing upon the subject of "colds and their consequences," gives the following useful advice: If you start to walk home from a down-town office, he said, and carry your coat on your arm because the walking makes you feel warm, you are liable to take cold. Therefore don't do it. If you should take the same walk after eating a hearty dinner, your full stomach would be a protection to you, but even then my advice would be, don't take the risk. A person properly clothed may walk in a strong wind for a long time without taking cold, but if he sits in a room where there is a slight draft, he may take a severe cold in a very few minutes. Therefore don't sit in a room where there is a draft.

Unless you are affected by peculiar nervous conditions, you should take a cold sponge bath in the morning, and not wash yourself in warm water. Plunge baths in cold water are not recommended, neither is it necessary to apply the sponge bath all over the body. Occasional Turkish baths are good, but those who have not taken them should be advised by a physician before trying them. Warm mufflers worn about the neck do not protect you against taking cold, but on the contrary render you extremely liable to take cold as soon as you take them off. They make the throat tender.

Ladies ought to wear warmer flannel underclothing than they now do, if one may judge from the articles one sees hanging in the show-windows of the shops. People take cold from inhaling cold air through their mouth often, perhaps, than by any other way. Ladies dress themselves up in heavy furs, go riding in their carriages, and when they get home, wonder where they got that cold. It was by talking in the cold open air, and thus exposing the mucous membranes of the throat. The best protection under such circumstances is to keep the mouth shut. If people must keep their mouths open in a chilly atmosphere, they ought to wear a filter.

Above all, be careful of your feet in cold damp weather. Have thick soles on your shoes, and if caught out in a rain which lasts so long as to wet through your shoes despite the thick soles, put on dry stockings as soon as you get home. But in cold, wet, slushy weather don't let them get so wet with overshoes. Rubbers are unhealthy, unless care is taken to remove them as soon as you get under shelter. They arrest all evaporation through the pores of the leather. Cork soles are a good invention.

When you go into the house or your office, after being out in the cold, don't go at once and stick yourself by the register, but take off your coat, walk up and down the room a little, and get warm gradually. Warming yourself up over a register just before going out in the cold is one of the worst things you can do. Never take a hot toddy to warm you up unless you are at home and don't expect to go out of the house again till the following morning. In short, make some use of your common sense, and thus emulate the lower animals.

HOW THE BODY IS BUILT UP.—The muscle and fat of the body, remarks the *Journal of Chemistry*, are derived from the food, and animal heat is evolved from their combustion or their combination with the oxygen admitted by the lungs. When the muscles are inactive, slow combustion goes on; and for every grain of carbon burned, a perfectly definite amount of heat is produced. When the muscles contract, the combustion is quickened, and the additional heat is liberated in the muscles themselves. If external work be done, as in lifting a weight or hammering a nail, the heat is no longer developed in the body, but transferred to the weight lifted or the raised hammer, and is liberated when they fall, and the heat thus liberated is exactly equal to the combustion inside the body. Thus the body is an apparatus efficient beyond all others in transforming and distributing the energy with which it is supplied, but possesses no creative power. A man weighing 150 pounds, by the consumption of a single grain of carbon can lift his body to a height of eight feet, and by the consumption of two ounces, four drachms, twenty grains, to a height of 10,000 feet. Mayer maintains against Liebig and others, that the muscles in the main play the part of machinery, converting fat into the motive power of the organism. He saw that neither nerves nor brain possessed the energy necessary to animal motion, and believed they held fast or let loose muscular energy as an engineer, by the motion of his finger in opening or closing a valve, liberates and controls the mechanical energy of a steam engine. These views are now quite generally accepted by scientific men.

BROWN-SEQUARD'S THEORIES OF THE NERVOUS SYSTEM.—With reference to the localization of the nervous system, the *Medical and Surgical Reporter* states that Dr. Brown-Sequard continues to announce that his experiments and researches prove that the doctrines of cerebral localization are erroneous and based on false assumptions. His demonstrations are striking. Thus, in an animal in which the right motor half of the pons varolii was incompletely divided, the left half of the hulk was afterward cut through, there remained no other way of communication between the two halves of the encephalon than by a small portion of the anterior longitudinal mass of fibers on the right side of the protuberance. Now, in this case, the galvanization of the motor centers at the right and at the left caused exactly the same movements in the limbs of the side opposite to the centers. The experiment was repeated a number of times, always giving the same results. It is observed by M. Grasset that the whole doctrine of Prof. Brown-Sequard is governed by two entirely new principles, viz.: 1st. All the phenomena which one ascertains after limited experimental or clinical lesions of a part of the cerebrum are produced by action at a distance. 2d. There are no agglomerated and circumscribed centers in the cerebrum for any function. There are certainly special cells, distinct elements, but these cells are distributed through the whole mass of the cerebrum. In other terms, there are no circumscribed, but diffuse centers.

A HYGIENIC LIQUEUR.—A friend of mine who has just returned from Germany invited me to a dinner party last week, and, at the close of the dinner—which was a singularly good one—an unknown liqueur was handed round, which was particularly recommended by the host and which no one could name. It turned out to be a new "German notion" of applied science to gormandize. The liqueur was a "pepsin essenz," invented by Prof. Oscar Lubruck, of Berlin, capable of digesting cast iron, and which the epicureans of the German empire propose to insure that good digestion shall wait upon appetite. On this occasion it did so, but whether the cook or the professor must hear the palm I cannot decide. I have seen an alderman include dinner pills among his dessert, and over this the "pepsin essenz," which has the flavor of a delicate hock, has some obvious advantages.—*London Truth*.

SANITAS.—Russian turpentine and water are placed in huge earthenware jars, surrounded by hot water. Air is driven through the mixture in the jars continually for 300 hours, the result being a decomposition of the turpentine and the formation of the watery solution of the substance, to which Dr. Kingsett, the discoverer, has given the name of "Sanitas." After evaporation, the substance, as sold in tin cans, is a light brown powder, of a very pleasant taste and odor, and capable in a very remarkable degree of preventing or arresting putrefactive changes. This new disinfectant has been in use for some time in England, and is highly spoken of. It is said to have a pleasant odor, is not poisonous, and does not injure clothing, furniture, etc. For household uses it would seem well adapted.

PRESERVING THE EYE.—Surgery can justly boast of a new conquest. When an eye is severely wounded the healthy one is in danger of being impaired by "sympathy." To preserve the good eye it was hitherto the practice to remove the injured one. Dr. Boucheron has discovered that by cutting the ciliary nerves the "sympathy" is stopped, and thus dispenses with the necessity of removing the injured organ. Forty surgeons have thus operated successfully.

The Week.

The recent storms, while they give assurance of an ample water supply for mining purposes, at the same time admonish miners that the winter season is upon us, and outdoor work, where weather exposure is required, must be brought to a close. The results of hydraulic and quartz mining for the past season have been satisfactory, and great preparations are being made for renewed activity as soon as the weather will permit. Prospecting in the various mining counties of this State continues to a certain degree, and good paying mines are being put upon the market. A common complaint made by capitalists is that applications for many mining claims are not made out at Washington. Miners should see that their applications are sent in as soon as possible, for just now capital is seeking investment in mines; but the mines must be in proper shape to secure an investment. A capitalist will not invest in a mine merely because you tell him it is a good one. You must apply for a claim on it, and show your faith by your works. The control of the Yellow Jacket and Hale & Norcross mines have passed, by purchase, from the Honanza firm, the former to R. M. Graves and William S. Lyle, and the latter to Alvinza Hayward.

The accident at the Union shaft, Virginia city, last Tuesday, is a warning to those who hold human lives in their hands to exercise extraordinary care. The injured miners have our earnest sympathy. A government mine inspector might possibly ameliorate the condition of the miner as to liability to fatal accidents through carelessness.

Congress is in session, but has not yet formed committees. The Nicaragua canal has received a end off, in the shape of a resolution, and Congressman Belford has introduced his mining law amendment, before alluded to in this paper. It is possible that the present session may examine into the debris question. It is certain at all events, that some move will be made in this all-important matter.

Trade-mark Law.

The recent decision of the Supreme Court of the United States adjudging the law regulating the registration of trade-marks to be unconstitutional, has naturally created a deep concern in the minds of those who are the proprietors of valuable trade-marks, and a doubt as to whether their property of this class has any future value or not. Much has been published since the decision which has a tendency to create false impressions, and these we desire to correct.

The Act of Congress.

Which has just been decided unconstitutional did not profess to create or destroy any lawful trade-mark. The right to such mark is a common law right, and has always been enforced. The object of the statute was only to allow of the registration of trade-marks at a central point, as a matter of convenience and proof. For this registration the party registering paid a fee, and obtained a certificate. With this certificate, he could sue in the Federal courts, while under the common law he would have to sue in the State courts.

The great benefit arising from registration then, was that jurisdiction was given to the Federal courts, and proof was made inexpensive. Registration was granted for 30 years. At the end of that time it could be renewed, or the owner could cease to be a registrant.

The Common Law Right

Would not cease, however, but would be made only the more certain by the thirty years registration. The more perfect means for the protection and enforcement of the right, which was provided by this registration, with its annexed penalties for infringement, are, of course, lost by the overthrow of the statute, and the owner is remitted to his common law right. This right is generally recognized, and some of the States have laws upon the subject, among them California.

The Law of California

Provides for the registration of trade-marks in the office of the Secretary of State, with penalties for the infringement of such marks, so that, with a certificate, the registrant is in position to protect his rights.

We give below a letter received by us from a law firm in this city, who have made the law of patents and trade-marks a specialty for many years, and whose opinion carries weight with it.

Present Status of Trade-marks.

SAN FRANCISCO, Dec. 3d, 1879.

MESSRS. DEWEY & CO.—You have requested a communication from us concerning the effect upon trade-mark rights of the recent decision of the United States Supreme Court, declaring unconstitutional and void the United States law which provided for the registration of trade-marks in the Patent Office, and protection of trade-marks so registered.

In reply, we have to say that the practical effect of the decision mentioned is of but little consequence. It merely leaves rights in trade-marks and protection for them just as they were before the said United States law was passed. Trade-marks are property now, and will be legally protected to the same extent and in the same manner as though the United States law had been declared valid. About the only difference will be that in most cases suits for the protection of trade-marks will be brought in the State courts instead of the United States courts, and in such actions evidence that the trade-mark was registered in the Patent Office will not be received. No trade-marks are destroyed or lost or impaired by the said decision. The United States law did not make or create or strengthen any trade-marks. It merely undertook to extend a protection to them under United States laws. That same protection, however, had been for ages extended to trade-marks by the laws of the different States in this country and by the laws of the various nations in Great Britain and Europe.

California has a trade-mark law which provides for registering the trade-mark in the Secretary of State office. It is not, however, necessary to register a trade-mark anywhere. A trade-mark becomes such by being used in trade, and when thus created, future infringements of it are prevented by injunctions granted by State courts, and damages for past infringements of it are obtained in the same tribunals, regardless of the fact as to whether or not such trade-mark was ever registered in any State or United States office.

We know of no reason why the California trade-mark law cannot be used with all the advantages with which the United States trade-mark law could have been used. It makes an official record of the trade-mark in a public office, and makes an authenticated copy of such record competent evidence by which the trade-mark can be proved in a court of justice. It also provides remedies for the protection of the trade-mark thus registered and punishments for its infringements. It practically does all that the United States law was intended to do.

WHEATON & SCRIVNER.

In this connection it is proper to add that we have just received advices from Washington, informing us that Congress will, undoubtedly, make an appropriation for the return of the fees which have been paid for registration, under the now defunct law. As soon as this is done, we shall inform our readers and shall also advise them as to the formalities necessary for its return.

Copper Mining in California.

Increased attention is being bestowed upon the copper mining interest in this State. New properties of this character are being brought into marked notice, and this valuable branch of mining interest now bids fair to assume its rightful position. Some of the mines that have long been worked are turning out increased quantities of ore, and an activity, that we hope may be long continued, is apparent in this direction.

California possesses the facilities, if they were fully in operation, of supplying the entire Pacific slope with all the copper it consumes in metal, or in the chemical salts of which it forms the base. It has the ores in sufficient quantity to yield all the copper that is used in sheet, ingot, wire, rivets or precipitate copper. In fact, if the copper properties were developed to their utmost capacity, no foreign copper would be required in the United States, for the supply could be amply met from this State alone.

Some few years ago quite a furore existed here in regard to copper mines, which led to much wild speculation and extravagant expenditure before the productiveness of the mines was ascertained. But, as in all such seasons of excitement, reason appeared to be cast aside and folly assumed its place. Such an unnatural condition could not long be sustained, and the explosion of the bubble soon ensued, being somewhat hastened by the decline in the price of copper which followed the termination of the war. Since then, with a few marked exceptions, the copper mines have been unnoticed. Many valuable veins of copper have been left unworked, and the greater portion of the field has been allowed to suffer from inertia.

The few companies that persevered in the exploration of their mines have been rewarded with success, and are now turning out monthly paying quantities of the metal. Their success has stimulated others to follow their example, and from this cause has arisen the attention which is given to this class of mines. It has been proved that if strict economy and business-like supervision are brought to bear upon copper mining in this State, that the profits are as sure as in any other mining operations that are paying dividends to their owners.

The ores are chiefly the sulphurets. Some of them will reach the average of 18% to 22% of copper throughout the vein. Others will run from these figures down to 5% to 8%. When intermixed with carbonates or with oxides they will be more than double the above percentages.

When the methods of working the ores shall have been brought to the same degree of perfection that obtains in older copper mining districts, the profits on copper mining will be very materially enhanced. In such case the by-products will all be saved, and that saving alone will pay the working expenses incurred in the reduction of the ore to metal. A great waste is allowed to exist in too many cases, which if checked would swell the profits. It takes time and experience, however, to overcome these errors.

At present the ores are piled in large heaps upon a layer of wood, which is set on fire, and the sulphur contained in the ore supports the combustion, until the ore is desulphurized. The ore is then subjected to the leaching process, and the copper is precipitated from the solution by the use of scrap iron. In some cases it is partly smelted at the mine after undergoing the roasting process, and in this concentrated condition is shipped to the refining works. In other cases the richer portions of the roasted ore are carefully culled out and shipped in sacks.

If much of the capital that is now devoted to stock speculation was judiciously invested in the development of the copper mines of this State, it would not only enrich the investors but would add to the general prosperity, beside affording occupation for an army of workers.

With a large number of mines in operation, reduction works would be established in the mining centers, and rolling mills would be put into operation. These would supply the copper wire and rivets, which are manufactured elsewhere, as well as the ingots, sheet copper and yellow-metal.

In a subsequent number of the PRESS, statistics will be presented showing the quantity of copper consumed on this coast, as well as giving the cost of reduction works and rolling mills, and showing the profits that would be derived from them. As a further encouragement to this branch of mining, arrangements will soon be consummated by which the producers of copper can obtain through the PRESS a weekly report of the ruling prices of copper in its different forms at the great copper marts of the world. With this information before him the copper miner can predicate closely as to the price he can obtain for his ores or the metal.

QUICKSILVER EXPORTS.—The exports of quicksilver from San Francisco during the month of November, by way of the sea, were as follows:

	Flasks.	Value.
China.....	800	\$25,320
Mexico.....	713	22,250
Chile.....	50	1,496
New Zealand.....	25	804
British Columbia.....	1	34
Totals.....	1,594	\$49,900
Previously this year.....	9,325	263,149
January 1st to Dec. 1st, 1878.....	10,919	\$318,055
Same time in 1879.....	25,947	857,380

Electricity as a Motive Power.

The great question which occupies the mechanical world at the present time is the suppression of distances. Steam and electricity have already produced such surprising results that human activity, aided by the incessant progress of science, continues to aim at still greater results. In addition to the telegraphic system, which transmits thought to limitless distances; in addition to steam, which has afforded us so many powerful manifestations; and in addition to the telephone, which annihilates distance and brings human speech from widely separated quarters of the globe into close contact—we stand now in the presence of a new problem, the solution of which is faintly presented to our view through the misty clouds which envelop the future. This problem is the distant transmission of power by means of electricity. It is many years since the question was first presented to the world, and that it is capable of solution is easily understood. The immense quantity of wasted forces are sought to be utilized—concentrated at some central locality, in the midst of a flourishing population, there to be brought into subjection, and augmented to vast proportions the public wealth.

With a view to solve this problem, savants have long been occupied with numerous experiments to convert electricity into mechanical power; but the feeble results of electro-magnetic machines have been from the commencement an obstacle, before which science has been compelled to halt, and the logical conclusion has been drawn, from a multitude of experiences, that it is as difficult to convert electricity into mechanical power as to manufacture diamonds from carbon. But latterly great strides have been made in the direction of success, as appears from the experiments at Sermaize, in France, where plying by means of electricity has suppressed distance and reduced the transmission of power to a practical issue. We have here the most curious as well as the most interesting demonstration of the great principle of the correlation of physical forces.

From a mechanical point of view this question of the electric transmission of power is not clear cut. It still remains in experiment, but will, in a short time, become a certainty. We can, even now, form a very correct estimate of the results which have been obtained. A distinguished engineer, M. E. Hospitalier, in giving a resume of all of the experiments with electricity transformed into a mechanical power, says (we translate from *La Correspondence Scientifique*): When a dynamo-electric machine is put in motion by a motive force of a given power it produces an electric current. This current, conveyed to a second and similar machine, is transformed again into a working or motive power, which can be utilized to the extent of 50% of the initial force required to put the first machine in motion. Numerous experiments upon the Gramme and the Siemens' machines leave this figure indisputable. Suppose, however, that the current is transformed into 20% only of the initial force, and we would produce immense results. Imagine a steam engine of 400-horse power located in a manufacturing center of Paris, and putting in motion a certain number of Gramme or Siemens' machines, thus producing enormous quantities of electricity, which could be transmitted in every direction by means of wires to a greater distance than one mile, we would have 100 effective horse power, with this great advantage, that the simple placing or displacing of a small wire would regulate the demand for power without special installments. Every horse power could be subdivided into a greater or less number of parts without diminishing the result, and as easily as can be effected with the electric light. We could, for instance, put in motion 10 sewing machines, 5 lathes, 3 card cutters and 2 saws in 20 different places with the current produced by one single machine, producing a one-horse power, and all the work performed by these 20 different industries, costing but 10 pounds of coal per hour. Would not the expense of rent, engineer, care, etc., be greater in comparison? These electric motors are not ponderous. One invented by Marcel Deprez, which will do the work of one man, weighs less than 37 pounds, while the motor for a sewing machine does not exceed eight ounces. These motors, it will be understood, are the mechanical means of transforming electricity into mechanical power. They produce neither steam or smoke, and cannot explode. They are easily transported, and are always ready, by simply attaching a wire, to perform faithful and constant labor. We can readily perceive that great advantages would result to industries requiring small power from a distribution of electricity, which would give motive power under such favorable conditions. It only remains to determine the value of mechanical results. That this will be done, is a question of only a few months, in spite of the prediction of W. E. Ayrton, in his lecture before the scientific meeting at Sheffield, that the realization of this power would not be effected before the next century. We have only to point to the practical results at Sermaize in France.

BAKER PASHA has gone to Asia Minor, to superintend the introduction of the proposed reforms there.

The Asbestine System of Sub-Irrigation.

This plan of sub-irrigation attracted much attention at the fairs during September and October last, it has already been introduced to practical working in Los Angeles, it is being discussed outside of the State as a possible means of securing considerable benefits—hence, we give upon this page engravings showing some of the leading points of the system, that it may be more intelligible to our readers who have not yet seen it.

The asbestine system is a California invention, letters-patent for it having been issued to the inventor, E. M. Hamilton, of Los Angeles.

It may be premised for the benefit of any who may have overlooked former mention of the system, that it consists in laying continuous cement pipe in trenches, through which the water runs by force of gravity from a reservoir above and is permitted to emerge here and there and saturate the earth beneath the surface, and thus irrigate adjacent trees and plants. The way in which this is done, may be learned by reference to the engravings, which are explained as follows:

In Fig. 1, A is the main pipe, supplying water from reservoir. B—Distributing pipes, laid about a foot below the surface of the ground, and about a foot from each row of trees; or, these pipes may be laid midway between the rows. C—Earth-guard, a piece of pipe, as shown in Figs. 3 and 4. H—Hydrant, or gate, as shown in Fig. 2. L—Spur from main. M, N—Connections between A and B through H, as in Fig. 2.

Fig. 2 shows the position of the hydrant as set. The plug-valve, V, being closed, water rises in H to level of water in reservoir; upon raising V, water takes direction of arrows, passing into B.

Fig. 3 shows the position of distributing pipe, B; earth-guard, C, four-inch caliber, set loosely on B, extending six inches above surface of ground to prevent earth from falling on plug; and plug, P. Water passes along B, flows up through the hole (O, Fig. 4) in P, and falls down on B, outside of P and inside of C, and is taken into the soil by capillary attraction.

Fig. 4 shows the relative position of B, C, P, and the tree; the dotted line representing surface of ground. The plug, P, is a tapering piece of wood, stone or metal, set in the pipe, B, having through it a tapering hole for passage of water. The reason of making it so is, that anything which can get into the hole with the water can readily pass through, and will not, by accumulation, close it.

The above, together with the engravings, will give a clear idea of the operation of the system when in place. One of the most interesting features of this system is the making of the pipe, and this is not shown in the engravings. This is done by means of an ingenious machine which works in the trench, and thus makes and lays the pipe all at one operation. This machine consists of a cylinder or case, which is laid horizontally in the trench prepared for the pipe. This cylinder is provided with a piston or plunger which is operated by hand, and which forms the pipe from the mortar or cement which is fed to the cylinder from a feed tube or hopper on top. A flexible core is attached to the end of the piston which forms the orifice through the center of the pipe; the pipe being thus made in a continuous piece without joints of any kind, so that all leakage is avoided. The operation of the lever attached to the piston, while it forms the pipe, serves also to force the cylinder or case along the trench gradually as the pipe is made and laid, by the same operation. In working the machine a man stands in the trench, at the end of the machine on which the lever is placed, and as he works the lever he moves along backwards in the trench. The cement placed in the hopper above, passes down readily through the tapering feed tube into the cylinder behind the piston. A stroke of the piston forces the cement back in the case and around the cone to which is attached the flexible core, thus forming the pipe and at the same time driving the machine ahead correspondingly, or about two inches at each stroke.

CURIOSITIES OF EARTH.—At the city of Medina, in Italy, and about four miles around it, wherever the earth is dug, when the workmen arrive at a distance of 63 feet they come to a bed of chalk, which they bore with an auger, five feet deep. They then withdraw from the pit before the auger is removed, and upon its extraction the water bursts up through the aperture with great violence, and quickly fills the newly made well, which continues full, and is affected neither by rains nor drouth. But what is the most remarkable in this operation is the layer of earth as we descend. At the depth of 14 feet are found the ruins of an ancient city—paved streets, houses, floors, and different pieces of mason work. Under this is found a soft, oozy earth, made up of vegetables; and at 26 feet, large trees, with the walnut sticking to the stem, and the leaves and branches in a perfect state of preservation. At 28 feet deep a soft chalk is found, mixed with a vast quantity of shells, and the bed is 11 feet thick. Under this vegetables are found again.

MR. HENRY H. MASON died in Carson City, Nevada, November 22d. Since 1860, when we first knew Mr. Mason in Sierra county, he has been in feeble health, and as an invalid has been faithfully cared for by a diligent wife. One act of his life will never be forgotten by the writer. When our entire printing office was burned, with the town of La Porte, in 1861, Mr. and Mrs. Mason tendered us the use of all their hard-earned accumulations to continue the publication of the *Mountain Messenger*. Honest and industrious, their purse was not as large as their hearts, but their hands were swift indeed to help their humble friends in time of need. That kindly act has ever since strengthened our faith in human friendship.

Amalgamating and Washing Ores.

We illustrated and described, some little time since, the Forster-Firmin amalgamator, but since that time several improvements have been added to the machine by the inventors. These improvements have specially the following objects in view: First, the introduction into the amalgamating chamber of two or more mingled streams of ore and mercury, said streams entering at different points in such a manner that they will impinge on each other, thereby effecting a more thorough mingling of the particles of ore and mercury than is effected when only a single stream is employed. Second, the provision of a series of settlers, so constructed that the passage of the ore through them may be continuous, the operation of these settlers effecting, however, the collection of the mercury or amalgam, permitting the same to be drawn off separately from the tailings.

By means of the peculiar construction and arrangement of the series of settlers, the mass of ore, water, etc., is conducted from one vessel to another, entering at or near the top of one, and discharging close to or at the bottom of such vessel, entering near or at the bottom of the next and leaving at the top, and so on. The

ARRANGEMENT OF PIPES IN ASBESTINE SUB-IRRIGATION SYSTEM.

effect of this is to produce a very thorough admixture of the mass, so as to bring any mercury or metal which may possibly have remained therein into intimate contact.

A still further effect is that such of the ore and amalgam as has become so finely divided as to float in globules on the surface of the water, will, to a considerable extent, be caused to collect, so that it may be scraped off, or will settle on the bottom of the settlers, where it may be drawn off through the ports.

NEW MAP OF THE COMSTOCK.—A new map, showing a longitudinal section of the Comstock lode, with the distribution of the ore bodies and underground workings of the principal mines, has been published by the San Francisco News Co., No. 415 Washington street. The map is colored and drawn so as to show quartz with low grade ore, depths of shafts, depths at which Sutro tunnel will drain, bonanzas or high grade ore bodies, vertical shafts and drifts, etc. The map is an excellent one for reference.

DRY WASHING.—We hear from a correspondent that Waugaman's new gold dry washing machine is now being manufactured at Los Angeles, and that Judge Peel, of Los Angeles, is working one of the machines 40 miles west of Fort Yuma. Samuel Eccles, of Silver City, New Mexico, has ordered one to work on the rich placers of that Territory.

Expanding Drill for Blast Holes.

John Julien, of Dubuque, Iowa, has devised a drilling machine for enlarging the lower or inner ends of holes for blasting purposes, so as to admit a large charge of powder being placed at one point. He uses a tube, having its upper end provided with screw threads, on which is screwed a jaw nut, and upon the end of the tube is screwed a cap, having radial arms. Through the center of the cap is passed a rod, having a thumb nut screwed on its upper end. This rod extends down to the bottom of the hole, and its lower end is forked and has a curved bit or cutter pivoted thereon. This curved bit or cutter projects through a hole in the side of the tube at the lower end, and within the tube is a slotted guide-piece which prevents the cutter being drawn up with the tube. After the usual hole has been drilled, this instrument is inserted in such hole to any desired depth and then rotated. The cutter is then, by screwing down the thumb nut, gradually fed outward through the slot, so as to make an enlarged chamber at the bottom of the hole for the purpose of applying an increased charge of powder.

SACRAMENTO DRAINAGE CANAL.—On page 359 of this issue, we give a short account of

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences, was held on Monday evening, Vice President J. P. Moore in the chair.

Among the donations to the museum, were a number of specimens of the mineral wax, found in Utah, and called ozocerite. It was made up in various forms, some representing fishes, etc. A number of candles formed from the substance were presented and burned readily. Dr. H. W. Harkness, the donor, said the wax was found in considerable quantities in Utah. So far, the largest masses have been found in the Rose mine, about sixty miles from Salt Lake City. The wax is black, quite soft, and easily melted. It can be bleached, and it is hoped to make it a valuable article of commerce. Ozocerite wax possesses many of the qualities of paraffine.

Capt. R. W. Simpson presented specimens of knots or excrescences resembling tubers, from the roots of Port Orford cedar trees. These "tubers" may be turned into balls and other shapes, and have a peculiarly handsome grain. The larger ones are found, however, to be worthless, being pithy inside. They are forms of abnormal growth, appearing in the ground at the roots of trees which have been injured by fire, or which grow in gravelly or inferior soil. Sometimes only two or three will be found at one tree, and again, hundreds will be found. Dr. Kellogg stated that they were akin to the bulbs or excrescences coming from the roots of cypress trees, but in the case of the cypress they appear above, instead of below ground.

Mr. Archibald Cooper presented a fossil fish from the Rocky mountains.

A number of specimens of spiders were received from a gentleman in Petaluma. They build their nests in holes in the ground. Mr. Moore described a "nocturnal spider," the habits of which he had studied. It has a hole in the ground and only appears at night, seeming to catch its prey by surprising it.

Charles Walcott Brooks called attention to the fact that there would be a total eclipse of the sun, January 11th. The eclipse will be invisible east of a line drawn through St. Joseph, Mo., and Baton Rouge, La. Visible to the western quarter of North America, the Pacific ocean, and extreme northern edge of Australia—being central and total along a line distant twenty miles south of and parallel to a line drawn through Monterey, Cal., Mariposa and Salt Lake City. Elsewhere it will be partial. The eclipse will begin as follows: Denver, Col., 4h. 1m. p. m.; Santa Fe, New Mexico, 4h. 1m. p. m.; Salt Lake City, Utah, 3h. 24m. p. m.; Victoria, V. O. I., 2h. 25m. p. m.; Portland, Or., 2h. 29m. p. m.; San Francisco, 2h. 35m. p. m.; Monterey, Cal., 2h. 38m. p. m.; Sacramento City, 2h. 39m. p. m.; Stockton, 2h. 40m. p. m.; Mariposa, 2h. 47m. p. m.; San Diego, 3h. 5m. p. m.; Virginia City, Nev., 2h. 48m. p. m.; the sun setting more or less eclipsed. At Victoria, Australia, the sun will rise on the morning of January 12th slightly eclipsed, the eclipse continuing for 15 minutes. Next year there will be six eclipses of the sun and two of the moon.

New Zealand Gold Fields.

Advices from the mines, per *Thames Advertiser* of November 8th, give encouraging news. The monthly crushing of "Alburnia" ore gave a better return than was anticipated, 307½ ounces of gold being obtained from 250 tons of quartz. The mine throughout is looking very well. At Dixon's low level the reef is about two and one-half feet wide, and colors of gold are frequently seen. 70 foot level, west: The manager is still driving on this reef, which keeps a good appearance, with fine looking minerals as work goes on. For the last 30 feet colors of gold were always seen when stone was broken down, and the manager's opinion is, that if the minerals continue, they will bring him on to richer gold than is being got at present. Stoping: Stoping has been commenced after this drive, and the manager hopes that something good will be met with before many feet are driven. 70 foot level, east: A winze has been sunk on this level, and is now down 16 feet. The reef is small, but shows colors of gold. Driving has been carried on at this level. The reef is not so wide as it was last month, but it is of better quality. It is now three feet wide.

Waiohahi: At the No. 3 level on the No. 4 reef, stopes 100 feet long have been opened up, the lode averaging six inches, and having a good appearance; more so as it ascends. 70 feet eastward have been driven on the No. 5 lode at this level. For the purpose of ventilating the low level workings, a crosscut has been driven from the No. 4, and in it a good bearing leader was met with. The drive on the No. 5 is about to be timbered up prior to commencement of stoping operations. Above the No. 2 level stoping is going on on a number of leaders, and a large quantity of crushing dirt is being obtained. A new reef, which is likely to turn out payable stuff, has been intersected on the hanging-wall of No. 5 above this level. It has been driven on for 30 feet, and is about eight wide,

The national debt was decreased \$799,823 during November.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same, appliances for testing, roasting, etc. Under the heading of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, waste of sulphur, etc. Under the heading of "Leaching processes" are the titles: Smelting, Mexican process, Chilean process, Krochuk's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for thinking a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three arrangements, amalgamators, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., Mining and Scientific Press, 202 Sansome Street, San Francisco.

ARITHMETIC MADE EASY BY ROPP'S EASY CALCULATOR.

This valuable work is used by thousands of farmers, mechanics and business men, and is highly recommended for its practical utility and convenience.

It embodies an entirely new system of calculation, by which a vast amount of figures and mental labor—required by the ordinary methods—and fractions with their complexities, are absolutely avoided.

It is so simple and easily comprehended that even the most illiterate is enabled, in a few minutes, to reckon with absolute accuracy and speed; while its original and rapid methods, benefit and delight the most scholarly.

It shows at a glance the accurate value of wheat, corn, rye, oats, barley, cattle, hogs, hay, coal, lumber and merchandise, from one pound to a car load, and for any price the market is likely to reach.

It gives the interest, simple and compound, on any sum, or any time, at six, seven, eight, and ten per cent.; the exact measurement of boards, scantlings, timbers, saw logs, cisterns, tanks, wells, granaries, bins, wagon beds, corn cribs, etc., the wages at various rates, for hours, days, weeks and months; besides numerous other important methods, rules and tables.

It is printed on fine tinted paper, is well and elegantly bound in pocket-book shape, and accompanied by a silk-cloth case, pocket for papers, and memorandum, which can be replenished in the two latter styles.

It answers the purpose of a pocket book and diary, and costs no more, although it was gotten up at great expense and labor, and is unquestionably one of the most useful publications ever issued from the press.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter or receipted by express. Address

DEWEY & CO., San Francisco.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy,

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-eight Years; Explorer, and Resident in the Pacific States and Territories for the past Twelve Years.

PRICE—bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the Mining and Scientific Press Office, by DEWEY & CO.

TO APPEAR SHORTLY.

Crimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. 8vo. Illustrated. By ROBERT CRIMSHAW.

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small Hand, Sash, Mill, Jig, Drag, Circular, Cylinder and Band Saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, iron, ivory, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, \$1.50. Orders for first edition received now.

CLAXTON, REMSEN & HAFELFINGER, Publishers, 624, 626, 628 Market St., Philadelphia.

The Explorers' and Assayers' Companion. (THIRD EDITION.)

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

ST. DAVID'S.

A FIRST-CLASS LODGING HOUSE.
CONTAINS 113 ROOMS.
715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional high top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upwards.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs,) S. F.

To Mining Men.

The undersigned, by the use of a Gold and Silver Indicator, is enabled to point out and trace with accuracy lues of Gold or Silver Deposits, whether in Veins, Mines or Gravel Diggings. Can tell whether the deposit is large or small, and near the approximate value.

For information address S. W. HOWLAND,
1804 Ellis Street, San Francisco, Cal

ALLEN GOVERNOR.

This Governor is now being generally adopted throughout the United States and Europe. It is without doubt the

Most Perfect Engine Regulator in Use,
And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised, it can be returned at our expense.

In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure.

Send for full descriptive circular.

Acknowledgement and Thanks.

LAKEPORT, Lake Co., Cal., Nov. 2d, 1878.
Messrs. DEWEY & Co., Gentlemen:—I hereby acknowledge receipt of patent, for which please accept my sincere thanks. When I have any further business in this line I shall certainly employ you. With kind regards, I am,
Yours very truly,
CHAS. SLATTERSECK.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of PHOSPHATE SOAP, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use PHOSPHATE SOAP.

For chapped hands the constant use of PHOSPHATE SOAP will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 21, 1879,
To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your PHOSPHATE SOAP as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.

SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:—
I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, *Pruritus*, the other an *Eczema*. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.,

126 O'Farrell St.
To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:—
I have tried your PHOSPHATE SOAP, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. HENRY H. LYNCH,
515 Haight street.

The genuine merits of PHOSPHATE SOAP and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-plumbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

Mines and Works of Almaden.

Translated from "Annales des Mines"

By S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

CONTINUED FROM PAGE 357.

obtained, is situated on a line with the Shamrock, and not a quarter of a mile distant.

TOMBSTONE.—A private letter to the *Citizen* says: The developments in the Tombstone mine are surprisingly rich; the assays show some of the ore to carry \$13,000 in gold and nearly \$10,000 in silver, and the quantity of the ore is beyond calculation. The mill is running very well.

ESPERANZA.—Judging from the report in the *Tucson Star*, this mine is a promising prospect. The shaft is down 100 ft, and a drift is being pushed to cut the vein. About 20 or 30 ft will have to be driven before this point is reached. There are three shafts at work. About three feet per day is accomplished. The ledge on the mine is very large. At the depth of 82 ft, where the shaft left the vein, it was nine feet wide. It is thought this width will not be diminished at the 100-ft crosscut.

COLORADO.

CUSTER COUNTY.—Silver Cliff *Prospector*, Nov. 24: The Dora smelter makes shipments daily of 35 to 100 bars of bullion, averaging 105 pounds to the bar. A car-load was also shipped from this smelter Friday, which we did not mention. We made mention a few days ago of some fine ore taken from the Sitting Bull, and gave as a surmise that it would run from 40 to 60 ounces. Messrs. Davidson, Metzler and McAnley have since made test by assay, the specimens running above 300. We learn the following of the Little Ed, a mine near Rosita. The owners, Messrs. Cornely, Metzler and Brant have sunk a shaft 30 ft and 31 wide. It gives an iron lead, mixed in with spar, horn silver and some chlorides. The Little Ed is about to be bonded for \$5,000. The Mountain Boy mine, situated in the range, recently opened by a party of gentlemen who have been quietly working away at their developments, now proves to be valuable property. At a depth of 25 ft the same kind of ore is found as that taken from the Silver King.

PRITCH.—San Juan *Prospector*: A writer says: The recent assays from the mines on the Ohio creek have created this rush. Gold, bright, glittering gold, as has not been recently found in Colorado, the extent of which is beyond the imagination of the most sanguine. Sample assays are as follows: The Dodson Lode, a true fissure vein of two ft, 60 ounces in gold and 40 in silver. The Golden Link, owned by the Campbell Bros., Folsom & Co., 30 ounces gold, 100 silver. The Ohio Lode, 70 ounces gold, 60 in silver. The Glidden Lode, 30 ounces gold, 20 silver. The last named is the property of Pennington & Co., and it is considered to be the biggest thing in the district, for although the assays are not so large as from the other mines, the lead shows four ft of gold-bearing rock, which, although but 17 ft has been reached, it is now widening, and its value is beyond estimate.

IDAHO.

YANKEE FORK.—The *Herald* of Nov. 22 publishes its promised "Mining Review," from which we make the following extracts: General Custer.—It is estimated that there is at least \$3,000,000 in sight at Mount Custer mine, and about 1,300 tons of ore on the dump, which will average \$200 per ton. Something over three months since active operations were commenced on this star property, and since that time the Pfeiffer tunnel has been advanced 120 ft. The vein was cut at the first 20 ft and proved equal in richness to that heretofore uncovered in the mine. A road is being constructed from the mouth of the tunnel to the most practicable place for an ore house, which will be connected with the intended 40-stamp mill on the Yankee Fork, 2,000 ft below, by a tramway. This roadway has been inclosed with substantial mining timbers, practically welded into the hillside, designed to protect it against the storms of winter. The plan for the ore house is a commodious and substantial boarding house has been erected, which will nicely accommodate 100 men. An excellent mountain road has been made from the Valley of the Yankee Fork to the mine. So far, the vein has proved to be about 10 ft thick, of high grade milling ore.

UNKNOWN.—This mine joins the "Custer." The vein was tapped by the Hyde tunnel at the distance of 12 ft. **GENERAL MILLS AND SILVER BELL.**—Large croppings of this mine during the past four months. The vein in the quartz at the mouth of the tunnel is seven ft wide, one and a half ft of which assays \$200.

HORE.—Lies about one-fourth mile east of Yankee Fork, and one-half mile north of Mount Custer. Cut and tunnel on the vein, both in quartz. At 20 ft from surface the vein is five ft high, between walls, two ft of which, in the cut, assays \$307 silver and \$130 gold. The walls are smooth and regular, and the ledge can be traced for hundreds of feet by the outcrop. Ore similar to that in the Custer. Numerous other locations on Mount Custer make a very rich showing.

CHARLES DICKENS.—This mine is situated on Norton hill, which is near the junction of Yankee Fork and Jordan creek, and about a mile and a half west of Mount Custer; \$10,000 of ore has been reduced by arrastra process from this mine during the past four months. The vein in the quartz at the mouth of the tunnel is seven ft wide, one and a half ft of which assays \$200.

DANIEL O'CONNELL.—Parallel with Charles Dickens. Tunnel in 80 ft on two-foot vein of \$150 ore.

OTHER MINES.—A cluster of locations exist which contain rich ores of gold and silver, assaying from \$50 to \$300, the greater part being gold.

MONTANA.—This mine in the above belt is considered the king mine. A tunnel was first run in 60 ft on the vein, about midway of which a winze is being sunk, and is now down 75 ft. The quartz vein is nine and a half ft in width, averaging \$300 per ton, two-thirds gold and one-third silver. The ore is very easily reduced; that worked here by arrastra process yielded 85% of the assay value. There are four grades of ore in the mine. The first-class samples over \$2,000 per ton; second, \$1,500 to \$1,700; third, \$400 to \$600; and fourth, \$150 to \$200. Over \$50,000 worth of shipping ore has been taken out of the shaft, which averaged \$1,500 per ton. There is from 100 to 150 tons of fourth class ore on the dump. In sinking the winze, \$1,000 was panned from the loose dirt, and from \$500 to \$1,000 per day in gold has sometimes been panned, in a hand mortar, out of rich specimens found in the ledge. Recently, 250 lbs of quartz assayed in a mortar produced \$18,000 in gold. The vein is in porphyry, and has been found at different points on the surface for a distance of 800 ft.

SNOWBIRD AND CHARLES WAYNE.—This mine is on the summit of the mountain, and has a tunnel on the north slope. Ore is found the whole length of the vein; in places 20 ft wide, and in this is a 2-ft vein that assays \$500. The Charles Wayne is 175 ft northwest of the Snowbird, and was the first ledge discovered on the mountain. There is a tunnel 60 ft on the vein, which is 100 ft below the crest of the mountain. The vein is 4 to 5 ft wide, and as the tunnel progresses the richness of the ore increases, approximating now \$500. The quartz carries both gold and silver, with considerable horn silver and free gold. The middle vein in this location is 7 ft in width with a 10-inch seam of high grade ore.

PIONEER.—Joins the Snowbird, and carries same grade of ore, with the exception that on the southwest slope of the mountain the veins are composed almost exclusively of gold quartz, some very large pieces being found rich in free gold. The best of the ore can be assayed up to \$3,000 per ton. There is a cut 60 ft long and 15 ft deep on the Pioneer, showing much good ore in a 2 to 2½-ft vein, with an 8-inch seam of high grade ore.

MIDWAY TREASURE.—Joins the Montana, and is opened by an incline 70 ft, and a level run from this 90 ft on the vein. The incline follows the ore body all the way down, and it continues of a very fair grade the entire length of the level. The vein is 6 ft wide, very uniform and averaging \$150 across the ledge.

MONTANA.

BONANZA CHIEF.—Helena *Independent*: A writer to an exchange says: In one place the fine, blue, crystalline rock yielded \$1 to the pan, and I have never seen a full pan tested that did not carry fully 20 cents when the rock was properly powdered. I measured the opening, and found it to be 60 feet across, in what was supposed to be the

direction of the lode, and transversely it was over 65 feet, and yet there are no walls. It is estimated that there are about 8,000 tons, including what is now on this dump, in sight.

JUDITH MINES.—Letter from Yago Gulch says: I understand the Benton mining company made a good clean-up last week on the rim rock. The gold was very coarse. I did not learn the amount of the clean-up. I prospected the rim on my own claim, with satisfactory results, but the rims don't amount to anything. The gulch ought to be good. If it is, it will pay for a bedrock flame, even if there is nothing on bedrock. A good many drain ditches are under headway at present.

Destruction of Government Timber.

The annual report of Secretary Schurz, handed to the President last week, contains the following passage, of special interest for Pacific Coast States, Colorado and all the Territories. After stating that the measures taken by the Interior Department for the protection of public timber have produced a good effect on public sentiment in many localities, he says: "It must be kept in mind, however, that the limited means allowed by Congress permitted a small field to be covered by these operations. The greatest danger of the wholesale destruction of our forests and of the disastrous consequences that destruction will bring after it, exists in those States and Territories where the timber indispensably required for domestic use and local industry must be taken from public lands, there being no timber lands in private possession; and the public lands being mostly unsurveyed and not subject to purchase or entry. In my last annual report I discussed the inadequacy of the laws enacted by the last Congress, authorizing citizens of Colorado, Nevada and the Territories to fell and remove timber on the public domain for mining and domestic purposes, and providing 'for the sale of timber lands in the States of California and Oregon and in Washington Territory.' The opinion I ventured to express, that the first of these acts would be taken advantage of, not only by settlers and miners to provide economically for their actual current wants, but by persons who would see in this donation a chance to make money quickly; that it would stimulate a wasteful consumption, beyond actual need, and lead to wanton destruction, and that the machinery left to this Department to prevent or repress such waste and destruction, through the enforcement of rules to be made by the Commissioner of the General Land Office, would be found insufficient for that purpose has already, in many places, been verified by experience; also, the predictions made by the Commissioner of the General Land Office with regard to the effect of the second one of the above named acts. Referring to what was said about these laws in my last annual report, I repeat my earliest recommendation, that they be repealed, and that more adequate legislation be substituted therefor. It is by no means denied that the people of the above-named States and Territories must have timber for their domestic use as well as the requirements of their local industries; neither is it insisted upon that the timber so required should be imported from a distance so that the forests in these States and Territories might remain intact. This would be unreasonable, but it is deemed necessary that a law be enacted providing that the people may lawfully acquire the timber required for their domestic use, and their local industries from public lands, under such regulations as will prevent the indiscriminate and irreparable destruction of forests, with its train of disastrous consequences. It is thought that this end will be reached by authorizing the Government to sell timber from the public lands, principally valuable for timber thereon, without conveying the fee, and to conduct such sales by Government officers under such instructions from this Department as will be calculated to prevent denudation of large tracts, especially in those mountain regions where forests once destroyed will not reproduce themselves. I have no doubt that under such a law, well considered in its provisions, the people of those States and Territories would be enabled to obtain all the timber they need for domestic as well as industrial purposes, at reasonable rates, and that at the same time the cutting of timber can be so regulated as to afford sufficient protection to the existence and reproduction of the forests, which is so indispensable to the future prosperity of those regions. I venture to express the opinion that the enactment of such a law has become a pressing necessity, and cannot much longer be delayed without great and irreparable injury to one of the most vital interests of the people."

The Secretary, referring to the enormous devastation of forests by fires left negligently burning or deliberately set for the purpose of deadening timber, recommends the enactment of some severe penalty, for willful or negligent setting of fires upon the public lands of the United States, and, also, for the recovery of all damages thereby sustained. He says it may in many cases be difficult to obtain testimony necessary for the conviction of persons guilty of this offense; but if the law is successfully enforced only in some instances, it will serve to direct general attention to the danger of incurring its penalty, and thus make many persons, who so far have given no thought to the possible consequences of their negligence or recklessness, more careful in future.

Secretary Schurz this year renews his previous recommendation for legislation to provide for the more speedy settlement of private land claims in territory acquired from Mexico, except California, which was provided means for the judicial determination of such matters many years ago.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

IMPROVEMENT IN MIDDINGS SCOURERS AND PURIFIERS.—George Summerton, 1422 Pacific street, S. F. Patented Nov. 18th, 1879. No. 221,751. In the ordinary machines for purifying middlings, difficulty is experienced in removing a peculiar fuzzy substance with which the middlings are intermingled. This substance seems to cling to the middlings in such a manner that it is not removed by an ordinary air blast, and can only be thoroughly removed by rubbing. It is not desirable to regrind this fuzz or light substance, and the inventor has therefore devised a means of scrubbing the substance under treatment so as to remove the fuzzy or light material from the middlings and blow it away, thus separating the valuable material from the dross. To accomplish this, a series of corrugated tables is mounted, one above another, in a cylinder or case, at the top of which is a peculiarly constructed propeller-shaped fan for inducing an air current or blast. In the center of the cylinder is a series of vertical circular diaphragms, corresponding in number to the number of tables, in the bottom of which are arranged circular rows of brushes which may be kept in contact with the tables, these brushes scouring or scrubbing the middlings on the tables so as to separate the light material which is drawn off by the air current. These diaphragms also answer the purpose of air tubes for directing the blast. Suitable arrangements are made for controlling the feed of material, for regulating the blast of air, and for adjusting the scrub of the brushes.

ATMOSPHERIC PUMPING SYSTEM.—W. P. Barclay, S. F. Patented Nov. 25th, 1879. No. 221,903. The improvements consist in providing at the surface of a mine an air-discharge cylinder or vacuum engine, connected by an air pipe with a series of atmospheric engines, situated at different levels in the mine, said engine being suitably connected with plunger force pumps. The air-discharge cylinder takes the atmospheric pressure or weight from opposite sides of the piston of the atmospheric engines alternately, so that these engines and their connected pumps will be operated at different levels by the one air-discharge cylinder, thus dispensing with all heavy pump rods. By this means, in a mine, for instance, two thousand feet in depth, instead of the pumps being worked by a massive engine on the surface, connected to the pumps by heavy pump rods extending the whole depth, with the attendant balance rod, boh, etc., the separate pumps are worked by the single air-discharge cylinder, as described.

AIR-COMPRESSING FAN.—Morgan B. Miller, S. F. Patented Nov. 25th, 1879. No. 221,970. The object of this device is to give a great pressure of air with comparatively small power. This is accomplished by making the arms or blades of the fan in a peculiar shape, like a con-

ical ogee curve, so that they will both draw in and force out the air with great facility. The heels of these fans, being made concave and projecting out by the edge of the case into the central opening, direct or throw the air into the center of the chamber. The faces of the fans are made convex, and the air is thus directed up the fans toward the periphery of the wheel. The outer ends of the fan are made convex, while the fans remain concave, and the air is thus blown with great force through an opening into the compression box or supplemental chamber. The fan is rotated very rapidly, and the air is forced into this box so strongly that it is more or less compressed, so that the pipes leading the air from the box convey the air, in a compressed state, to the point of issue. A very strong blast is obtained in this way without any undue expenditure of power, and this class of blowers thereby very much increased in efficiency.

INVALID BED.—James H. Archer, S. F. Patented Nov. 25th, 1879. No. 221,952. In the construction of this invention, a peculiarly divided hinged or jointed bed-bottom is used, having a supplemental leaf hinged to it, and, in combination with this bottom, a series of folding, adjustable standards with cords and pulleys, together with a roller, crank and ratchet, by which the bed-bottom is raised and held at any point. With this roller and the jointed bottom, curved links or hooks are employed at different points upon the bed-bottom, and also upon the roller, so that by shifting from one hook to another, one set of cords will serve to make all the adjustments which may be needed. The standard may be folded down so as to be concealed, and the bed present an ordinary appearance when desired.

VACUUM ENGINE.—B. Goldmann, San Francisco. Patented Nov. 25th, 1879. No. 221,961. This invention relates to a novel construction for a vacuum engine; and it consists in the employment of one or more cylinders having suitable ingress-valves, by which an explosive or inflammable gas or vapor may be admitted and ignited. The surface of the piston or pistons is open to the action of atmospheric pressure, and when the vacuum is formed beneath the piston it will be depressed. Suitable operating-levers and connections serve to move the different parts.

IMPROVEMENT IN TRUSSES.—Geo. Gleim, Yreka, Siskiyou Co., Cal. This device relates to an improved truss such as is used in the treatment of hernia, and consists in certain details of construction by which the pad is kept in its exact position, while, at the same time, freedom of motion is allowed to the plate to which the belt or band is attached for keeping the truss in place. Once regulated the pad is immovable and the truss self-adjusting. This construction may be applied to single, double, umbilical, and all other kinds of trusses, which may be made of any suitable material desired.

ACCIDENT AT THE UNION SHAFT.—A frightful accident happened at the Union shaft, Virginia City, last Tuesday. B. F. Corliss, engineer at the Union shaft, on changing shift this morning, ran the cage and skip into the sheaves. Eighteen men in all were on the cage and in the skip under it. The skip is itself a self-dumper, and the engine was set to running at such a speed that eight out of nine men in the skip were thrown from 12 to 20 feet over beyond the chute and upon the floor. Out of nine men on the cage, all but two jumped off. After dumping the skip, both cage and skip were raised about 40 feet, and when the sheave was struck, the new wire cable, seven inches wide and three-fourths of an inch thick, was snapped like thread, and the whole building terribly shaken. Nearly all of the men were injured and two were killed or have died of the injuries received. When the cage struck the sheave and the rope broke, the safeties held it, and the men were seen hanging about the shaft and timbers like flies on branches. Mahle says that 600 feet from the top, the engineer commenced increasing the speed of ascent; 250 feet from the surface another increase was made, and when they came to the surface it went faster yet. The only possible explanation given is that the engineer, in place of shutting off steam, had unwittingly turned more on. The indicator to the engine had been stopped a few days before to repair it, but the rope was well tagged, and no excuse is offered for the carelessness of the engineer.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Hillside, November 29th, \$3,500; Northern Belle, November 29th, \$9,240.14; Christy, December 1st, \$7,077.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

ARIZONA CONCENTRATING CO.—Object: To carry on the business of milling and mining in Arizona Territory. Capital, \$100,000. Directors—Charles M. Seelye, Edward W. Stephens, Charles E. Travers, Joseph Tyson, Walton Townsend, Edward Reilly and D. L. Dyke.
MOUNT DANA M. CO.—Object: To mill and mine in Tioga district, Mono county. Capital, \$1,000,000. Directors—J. M. Walker, Edward W. Frey, E. M. Hall, G. W. Hopkins and John F. Bradley.
EASTERN BELL & S. M. CO.—Capital, \$10,000,000. Directors—J. L. Callison, N. K. Masten, F. Locan, Wm. F. Booth and A. J. Ralston.

News in Brief.

MICHAEL CHEVALIER, the political economist, is dead.

The miners of Cambridge valley, Ohio, are on a strike.

The Bishop of Massai, Abyssinia, has been imprisoned by King John.

The Indian outbreak in Colorado is again assuming unpleasant features.

GRANT does not expect to visit Washington until his return from Mexico.

A NEW reservation, in some of the Territories, is to be selected for the Utes.

SERIOUS Indian troubles are reported from Texas, many whites having been massacred.

CHIEF O'RAY has been presented with a watch for his friendship to the whites.

The poor in the southwestern portion of Ireland are suffering for want of necessities.

The Sidney-Australia exhibition has received only \$70,000 against \$1,115,000 expenses.

ALL of the newly elected officers of San Francisco took their seats on the 2d of December.

An extradition treaty between the United States and the Netherlands will soon be adopted.

FLOOD & Co., have disposed of their interest in the Hale & Norcross and Yellow Jacket mines.

The Cuban insurgents have met with a serious reverse in the Province of Santa Clara.

The coal companies of Pittston, Pa., have voluntarily advanced the wages of the miners 10%.

Two representatives of the French government are in New York inspecting postal facilities.

PULSIFER, of the Boston Herald, is now the nominee of all parties for Mayor of Newton, Mass.

CHIEF DOUGLAS has returned the money he stole from Mrs. Meeker at the time of her capture.

THREE THOUSAND women are registered in Massachusetts for the coming municipal elections.

THREE Catholic Bishoprics are to be established in America, under the Archbishop of New York.

SPECIE received at New York from abroad from January 1st to date, aggregates \$77,184,080.

PATRICK CROWLEY has been chosen by the San Francisco Police Commissioners as Chief of Police.

The Atlantic and Great Western railroad is to be sold under foreclosure at Akron, O., January 6th.

SILVER in London 53½d; consols, 97 5-16; 5 per cent United States bonds, 105½; 4s, 106½; 4½s, 109½.

A HEAVY land slide in Niles canyon is causing considerable trouble to the Central Pacific Railroad Company.

BRITISH iron workers are cautioned in an address not to emigrate to America until assured of employment.

SIXTEEN Revenue Deputies have been captured by "Moonshiners" in Georgia, one being badly wounded.

At Liverpool wheat is quoted at 10s 7d to 11s 6d for average California white, and 11s 6d to 11s 10d for club.

YAKOOB KAHN has departed from Cabul, which is said to mean that Afghanistan has seen the last of its Ameer.

In San Francisco half dollars are quoted at par; trade dollars, 96 buying, 96½ selling; Mexican dollars, 96 buying, 96½ selling.

In New York Government bonds are quoted at 102½ for 4s of 1907; 102½ for 5s of 1881; 105½ for 4½s; sterling, \$4.81½@4.84; silver bars, 114½; silver coin, 104½ discount.

The Czar of Russia is about to establish reforms in the Government, and proposes to call a number of unofficial advisers to assist him.

CONGO MINING DISTRICT, NEVADA.—This is a new mining district, and was organized on the 20th of September, at a meeting of miners held at Paradise, Humboldt county, Nevada.

The boundaries of this new district are as follows: Commencing at the termination of T. J. Bradshaw's road, on the summit of the mountains, adjoining Rebel Creek district; thence south along the eastern boundary of said Rebel Creek district, to the Shaw district; thence east to the southeast corner of David Abel's ranch; thence north to the northeast corner of John Byrnes' ranch; thence west to the point of commencement.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send one but worthy men.

J. L. THARP—San Francisco.

B. W. CROWELL—California.

A. C. KNOX—Pacific Coast.

S. V. BRADSHAW—California.

G. W. MCCORMY—Santa Clara county.

J. B. BACKLIDER—Shasta County, Cal.

JAMES ROBERTS—Oregon and Washington Ter.

THOS. H. MANNING—Nevada, Idaho and Montana Ter.

CAPT. W. H. SEAMENS—Arizona.

M. P. OWEN—Santa Cruz County.

H. E. HADLEY—Los Angeles County.

T. H. ORGAN—Alameda county.

M. B. STARR—Contra Costa county.

J. D. BASNETT—State of Nevada.

THE INTERNATIONAL HOTEL, advertised in this paper, is one of the popular hotels of S. F. None other has so long held an equal reputation. Travelers wishing comfortable accommodations at very reasonable rates should try the International, and they will get fair treatment and value repaid for their coin.

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	
1870	20	2 Complete volumes, 1st half (of year).
1870	20	2 Copies of No. 2, Jan. 1st.
1870	20	1 Copy each of No. 1, Jan. 1st, 3 of Jan. 11th, 7 Feb. 11th, 6 Feb. 4th.
1870	21	1 Copy of No. 7, August 13th.
1871	22	5 Copies of No. 1, Jan. 7th.
1871	22	8 Copies of No. 5, Feb. 4th.
1871	22	1 Copy of No. 3, Jan. 21st, 6 of Feb. 2d, and 1 of May 1st.
1871	23	1 Copy of No. 2, July 15th, and 9 Sept. 2d.
1872	24	2 Copies of No. 4, Jan. 27th.
1872	24	3 Copies of No. 7, Feb. 17th.
1872	24	2 Copies of No. 17, April 27th.
1872	25	1 Copy of No. 10.
1872	25	1 Complete volume, last half (of year).
1873	26	3 Copies of No. 8, March 1st.
1873	26	2 Copies of No. 10, March 8th.
1873	26	1 Copy of No. 7, Feb. 15th.
1873	27	3 Copies of No. 20, Nov. 15th.
1873	27	4 Copies of No. 21, Nov. 23d.
1873	27	3 Copies of No. 24, Dec. 13th.
1875	30	1 Copy of No. 4, Jan. 23d.
1875	30	1 Copy of No. 5, Jan. 30th.
1875	30	1 Copy of No. 8, Feb. 20th.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Cruber's great calculator, the Zographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed under-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flooring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

Secure Patents and TRADEMARKS.

Through Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. **DEWEY & CO., PATENT AGENTS.**

Miners, write for your paper.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claim from July 20th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco.

The Electric Light.

We see by the New York papers that Thomas A. Edison is shortly to exhibit that long looked for achievement of science—the economical subdivision of the electric light. On Christmas eve Mr. Edison promises to illuminate the buildings in the modest little bachelors' hall in which he lives and works. To that end wires have been run from house to house, and connected thence with his laboratory. The illumination will be by means of what might be called electric jets, but which, more properly speaking, are small spirals of platinum and iridium in a state of incandescence in a vacuum. The dynamo-electric machines, whence the current is generated, are already set up in the laboratory. One of these, having a power of forty horses, will generate sufficient electricity for 160 lights, each of 16-candle power, which is the measurement of electric intensity. That is to say, the extraordinary phenomenon may be seen on Christmas day in Meulo Park of electric lights toned down to the intensity of gas jets. In a few days Mr. Edison will begin the task of affixing the jets, so called, upon the gas burners in the several houses. Instead of running the wires that are to transmit the current through the gas pipes, as it is his intention to do shortly in New York, for this occasion he will lay the wires along the pipes.

"I shall send invitations far and wide," said Mr. Edison to a reporter, "in order that all may see that what has been considered as visionary and impossible has been accomplished. The thing is done. I have protected it in this country and every considerable country in Europe. That is to say, there are only a few unimportant parts of Europe yet remaining uncovered, and these will be so before the advent of the holidays. You ask me if I can compete with carbureted hydrogen gas. Let the gas companies reduce their price, and then reduce it again, for it is well known that they can still do this and make money, and I can undersell them and make a large profit." Everybody will watch with interest the results of this proposed exhibition, and Mr. Edison's strong confidence in his plan is not likely to have been gained without being very certain of his premises.

Many others, besides Mr. Edison, are devoting themselves to the perfection of appliances for utilizing electricity as an illuminating agent. Experiments are being conducted on both land and sea. The electric light was not long since experimentally used in the saloon of a new steamer, *Mendoza*, belonging to the Pacific Steam Navigation Company, as she came around from Liverpool to Glasgow. The satisfactory result of this trial is now manifested by the fact that the Pacific Company have entrusted the British Electric Light Company with the work of fitting two electric lights, produced by means of Blandy's patent, from one small Gramme machine, in the saloon of the *Mendoza*. This ship is intended for services on the west coast of South America, and is a beautiful vessel, specially designed and adapted for the particular trade for which she was built. The saloon of the steamer is very large and tastefully decorated. The particular method of applying the light, which has been selected by Mr. Radcliffe Ward, the electrical engineer to the British Electric Light Company, is by reflection from special reflectors in the ceiling of the saloon. The result is a beautifully diffused soft light that effectively exhibits the tasteful painting of the saloon panels.

The success of the light on board the *Mendoza* will doubtless lead to the adoption of similar lighting on board all the principal ocean steamships before long. The illumination of the state-rooms by the incandescent system, in one form or another, is likely to be accomplished ere long. The boon to passengers of being able to turn on a bright settled light at desire will be very great. In this case the light will be placed in globes hermetically sealed. It will be seen that the electricians are doing their best to justify the hopes they raised a little time back.

A BERLIN correspondent announces that the German government will resume the sales of its superfluous silver.

A New Fruit Gathering Apparatus.

We give on this page an engraving of a device for gathering fruit, invented by L. H. Titus, of San Gabriel, Los Angeles county. A hook *A* hangs at the top round attached to a cord with a weight at the bottom, a knot being made on the cord near the hook. The branches may be pulled in with the hook, and the cord passed around the button or the bottom-sides of the round. The branch is then held in a convenient position, and both hands may be used to pick with.

B is a hopper, and is made of canvas or cloth, with a spout running into the basket, having a rubber band across the bottom to break the fall and let the fruit in gently. The inventor says that eggs may be dropped from the top of the ladder into the hopper and run through the spout without breaking.

C is a bale or brace which holds the ladder at

TITUS' PORTABLE LADDER.

a right angle; it passes over a rod that runs through the ladder and is notched on each under side, the notches fitting on the rod, making it an easy matter to control the angle of the ladder, it being hung at the bottom on two stumps with a rod passing through the ladder, making it hang on a hinge.

A ladder 30 feet high can thus be easily handled, and the fruit gathered without being bruised. A representative of the *PRESS* recently saw this device in use at San Gabriel, where it appeared to give good results. It does not need any support, so that the limbs of the trees are not apt to be broken. Spikes are placed in the points of hearing which enter the ground and keep the device in position. It may be moved by simply bearing down on the handles and wheeling off in the same manner as with a wheelbarrow or hand-cart, carrying baskets, hook and hopper with it. Manufacturers or other parties wishing to buy county or State rights should address the patentee as above.

THE St. Gothard tunnel makes steady progress, no less than 3,000 workmen being engaged upon it. Nearly 10 tons of dynamite are used per month.

THE spinners of Oldham, England, demand 10% increase in wages.

DEATH OF A VETERAN MINER.—Capt. Williams, of the famous Van mine in Wales, died about two weeks since. His life has been very eventful and is a striking illustration of force of character and indomitable perseverance, combined with honest industry, which surmounted every obstacle. After being connected with many mines, he began working the celebrated Van in 1854. He continued in the management until his death, a period of about a quarter of a century. It was in the year 1865 that he cut the great productive lode, and so confident was he of the certainty of this great discovery to his made that he conducted the management, for a period of eight years, up to 1865 gratuitously. He did this to encourage the proprietors, and in furtherance of what he esteemed his life work. In 1868 he took exclusive charge, and since then he carried out the developments underground and on the surface, which have rendered the Van mine possibly the most celebrated of its kind in Great Britain. Many great improve-

Why Our Copper-Mining Interest Should be Encouraged.

With an almost culpable degree of shortsightedness in the capitalists of the Pacific slope, the very important branch of industry of copper mining has been suffered to languish and to be almost extinguished. With a copper field unequalled in its extent by those of any other portion of the world, it has been so completely ignored that the vast treasures which it contains are now lying dormant in the veins and ore beds. This inertia exists regardless of the fact that the copper consumed on the coast amounts yearly to several millions of dollars in value. This sum has to be sent away from our shores to other ports, for the purchase of what is only awaiting the encouragement of capital to be produced here, and thereby not only increase our home wealth to that amount, but also to keep for home circulation the money now expended for it. The shipments which would be made of the surplus product, would bring back to us a large amount of coin, thereby augmenting our local wealth.

Ingot copper has advanced about 43% in price within the last few months, and is still appreciating in value. This advance will increase our shipments of coin to pay the excess in price, and we consequently lose the benefit of it, which would have inured to us, if our copper mines had been duly sustained during this past few years.

Had this been done thousands of workers would now be employed, and the wages they would receive would be in circulation among us. New mines would be opened and a wider field would be brought into profitable operation; adding to the value of now almost unnoticed properties, and giving rise to new industries closely associated with the copper interest. Smelting works would have been erected and rolling mills established in this mining centers of the coast.

This latter branch of the copper industry could now be successfully maintained, and a safe field for investment is awaiting such capitalists as may have the spirit to foster this department of labor, which has ever been in other localities, where such works have been put into operation, a source of profit to their owners. They would also react to the advantage of the investors, inasmuch as they would incite prospectors to discover new veins, and by thus increasing the quantity of copper produced, give an additional impetus to the copper interest and an enlarged scope to the business of the furnaces and mills.

It would require a paid-up capital of \$300,000 to establish this industry. It would take \$150,000 of it to erect and put in operation a well appointed rolling mill with all the necessary machinery for turning out sheet, bar and wire copper; also to make copper bolts, nails, rivets and yellow-metal. This balance of the capital would be required for the business of the enterprise, in the purchase of copper and incidental expenses needed to its successful advancement.

The duty upon foreign copper is as follows: Pig, bar and ingot, 5 cents; old copper, 4 cents per pound. Manufactured and copper nails, 45%; yellow-metal and zinc nails, 35%, *ad valorem*; all else, 10%.

The last Eastern advices give the following market quotations: Firm and active. Sales one week ingot copper 850,000 lbs. @ 21 1/2 cts. cash; 22 1/2 cts. for February delivery.

Copper sheathing and nails.....	22 cents.
Yellow-metal sheathing and nails.....	13 "
" bolts.....	25 "
Copper nails.....	24 "
Brazier's copper, in all sizes, from.....	24 to 30 "
Old copper.....	16 "
Old yellow-metal.....	8 "

The quotations of the Eastern markets will hereafter be given weekly, for the benefit of the copper-mining interest.

MR. PETER STAINSEY, at one time known as "the great mining king" in England, died recently at his residence in London. At one period he had invested in lead and tin mining companies half a million sterling.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

I. X. L. District, Nevada.

EDITORS PRESS:—This district is situate in Churchill county, Nevada, distant about 25 miles from Stillwater, the county seat of the above county. It is less than a year since the developments I am going to mention have come to light. Yet it is no new discovery or wildcat excitement, for as early as the year 1861 several prospectors located here, but having no means to reduce the ore, they finally abandoned it. The following year, 1862, the Yankee Blade district excitement broke upon the mining world with great promises for the future. Several of the best citizens of Nevada rushed forth to the new El Dorado, among whom were ex-Governor Bradley, John G. Post, Abe Edgington, Al. McCausland, and others, but met with the same results that their fellow prospectors met with one year before, and from the very same cause—no means of reducing the ore.

Last year a party of prospectors visited Eureka, among whom were John L. Colvert, Pete Maloney, Mr. Higgins, and others, and called on Mr. J. S. Allen, of the Ottawa hotel in that place, and showed to him some samples of ore from the I. X. L. district. Mr. Allen had the samples assayed, and the following returns were obtained: East Star mine, from four samples, highest \$500.37, lowest \$104.28; Bayfield mine, returns from five samples, highest \$1,008, lowest \$98.73; Gilroy mine, six samples, highest \$964.40, lowest \$310.80. Mr. Allen at once left Eureka, and visited this place, and found the different ledges even better than they were represented to be, and at once set to work to open some of the leading prospects of the place, among which are the East Star, Bayfield, Gilroy, Stonewall Jackson, and a host of others too numerous to mention here. Mr. Allen has displayed the greatest tact since he has visited this district, and it is due to his good management and liberal patronage that the district appears as it does to-day.

There are about 50 men here at present, and parties coming in daily. But it is not our wish that anyone should come before spring—beyond agents or experts to examine the district—for as yet no accommodations have been made to receive families or others that are not used to roughing it. In the early summer, a fine 20-stamp mill is to be built; and as a beautiful town site has been already laid out, we feel that I. X. L., ere another year rolls around, will take her place side by side with many of the hulloin-producing camps of Nevada.

The main ledge in this district can be traced for at least a distance of eight miles, and at any place that has been touched, it has not failed to give rich assays—some of the returns you have read above. There is an abundant supply of wood and water in the immediate vicinity of this place, and a most beautiful climate. From its sheltered location and broad, sunny valleys that lie adjacent to the district, almost anything that is grown in California can be raised here with success. Cereals and hulloin roots of all kinds cannot be excelled in any part of the Pacific coast; features that will go forth to make it one of Nevada's producing towns when the lesser and more barren camps of the State will have passed to oblivion.

This district is at present well worth a visit from some of the leading mining men of the Pacific coast. There will be very little lost in paying this place a visit; but, on the contrary, all to gain by investing in it, for every mining district has to be discovered before developed; therefore, gentlemen, come and see for yourselves. Should it prove to be a second bonanza, all right, or a much less object (say one that would add many millions of dollars to the general commerce of the country), it would be no mean affair; the latter object is now in sight, only awaiting the touch of capital to develop it. I. X. L. district is a field well worth the investigation of capital, and he who comes first will have the best showing. The best way to come here is by way of Austin, this State, where full directions will be furnished to travelers wishing to visit this place; or Wadsworth, via Stillwater, as parties may desire.

T. L. CONRAN.

Nov. 24th, 1879.

IMPORTANT TO BREWERS.—Judge Dyer, in the United States Circuit Court at Milwaukee, Wisconsin, on Dec. 2d, decided the case of Matthew Godfried against the Philip Best brewing company, sustaining the complainant's patent. The decision is of great importance to brewers, as it makes them liable for royalty for the use of the process and apparatus for pitching the inner surface of kegs and barrels, which have been in use in large breweries for several years. It is understood that other large brewers, including those of Illinois and other States, have stipulated to abide by the decision, subject to its confirmation by the Supreme Court.

THE total production of anthracite coal for this year is estimated to amount to about 26,500,000 tons, or about 3,750,000 tons more than was ever before produced in one year, and 8,250,000 tons more than was produced last year.

Wood River Region, Idaho.

The *Yankee Fork Herald*, of November 22d, contains new and interesting information concerning the mines of Idaho. Speaking of the wealth of the Wood River region and the magnificent showing in the base range, it says that this season is the first time in which it began to attract the attention of prospectors and miners to any great extent. For several years past it was no secret that galena ores were abundant in that portion of Idaho, but discoveries and developments were limited until the past summer and fall. The prospects of an early railroad from some point on the Utah & Northern through to Oregon, and passing near the Wood River mineral field, stimulated prospectors to turn their attention in that direction. It is gratifying to note that their efforts are rewarded with many rich finds.

So far, four or five different galena belts have been opened up, and it is the belief of all who have explored in that section, that belt after belt of argentiferous galena ores exist all the way from the low hills at the base of the Wood River range to the divide of Wood and Salmon rivers, a distance of 45 miles. In length this great belt of high-grade galena and carbonate ore extends in a southwesterly direction from Bay Horse district, near Challis, through by the head of East fork to Wood river and over to the south tributaries of the Boise. This makes the most extensive base range known, being from 20 to 40 miles in width and in length from 130 to 140 miles.

In the mines of the Lower Wood River district, which are divided into two camps, known as Jacobs' and Callahan's, the veins vary in thickness from one to two and one-half feet. The ores are galena, easily smelted, running from 40% to 60% lead and from \$80 to \$250 silver. There is an abundance of iron in the vicinity. The leads are generally well defined with bold croppings. It is a well watered and wooded section, and the hills are covered with bunch grass. It is a mineral country all along the base of the mountains, and once the railroad is completed thus far, the ore will be brought to easy market. The first mines were discovered in 1877 by a man named Jacobs, from whom the camp takes its name.

The distance from the old emigrant road to Bonanza via the Wood River and Saw Tooth districts is about 103 miles by the survey.

This ore in Callahan district, six miles above Jacob's Camp, on the main Wood river, is similar to that found in other parts of Wood river, carries a large per cent of lead and considerable oxide of iron. The ledge is four feet wide, with a vein of good smelting ore two to three feet running through it. The Callahan is the best developed mine on the river. There are eight or ten leads besides the Callahan, equally good and strong as the latter. The ore is easily reduced, carries about 60% lead, and from \$150 to \$300 silver per ton.

The climate is favorable for a winter camp. Wood, water and grass are not lacking in quantity or quality.

The Warm Spring Creek mines give promise of developing into important producers of lead and silver. The creek is a tributary of Wood river coming in from the west and is properly the west fork of Wood river. It is about 20 miles above the emigrant road, and nearly midway between Upper and Lower Wood River mines, hence the camp is sometimes mentioned as Middle Wood River district. The mineral belt is located about 10 miles from the mouth of Warm Spring creek, and was discovered the past summer by James Steele, John Boyle and Billy Short. The first mine, the Idaho, located June, '79, by Boyle, Giles, Kinney and Butler. There is an open cut 20 feet long and 15 feet deep on the ledge, exposing a large body of antimonial silver ore that assays from \$80 to \$205 per ton.

Wood River is the next location on the creek, made by Boyle and Giles and adjoining the Idaho. Shaft 10 feet deep on the vein, showing a good body of ore that assays on an average \$150 per ton; is in porphyritic granite, showing considerable iron, formation loose but not broken.

Black Horse—Discovered and located by John Boyle. Shaft and open cut exposing two feet of galena ore, that assays over \$300 per ton silver and 40% lead. Formation lime. Ten Brock—Located by Moffitt and Ervin, in August last. From 12 to 15 inches of galena and antimonial silver. The vein is exposed for nearly 100 feet by shafts and open cuts, with a "blow out" of several tons of ore. Assays from \$150 to \$275, and 40% lead. The ledge cuts the country rock, making a true fissure vein. Ervin—This is a contact vein lying between the lime and granite—granite foot wall and lime hanging wall. Ledge six feet two inches wide, showing four feet of galena ore assaying from \$140 to \$245 silver, and 40% to 60% lead. Shaft on discovery 15 feet, cutting the vein. Open in a number of places; 300 feet from discovery is a cut on the vein, which shows from four to five feet of galena, with small quantity of oxide of iron. Discovered by Ervin and Moffitt. Sovereign—Discovered by Wm. Thompson, on Thompson creek, a tributary of Warm Spring creek, about one mile from the Idaho. An open cut on the ledge 16 feet from the surface, showing a magnificent body of gray carbonates, that assays from \$200 to \$900 per ton silver and 45% lead. The croppings are large, showing thousands of tons of ore that assay \$30 to \$35 per ton. Indian Boy—Extension of the Idaho on the north, located by Wm. Thompson. This is a small vein, well defined, carrying ore that

assays from \$100 to \$300 silver. Developments limited. Ontario—Owned by Chambers, Hathaway and Rooks. Vein 18 inches, averaging with the other ledges of the camp. Hathaway, Niagara and North Star—Similar to the Ontario, and owned by the same parties. Comet and Accident—Located by Sullivan and Mulky. Opened by shafts at different points on the vein, showing extensive bodies of antimonial and galena ores. Gopher and Old Abe—Located by Ervin and Moffitt. These are well-defined ledges, developed by open cuts, showing prominent veins that assay from \$400 to \$600 silver and a few dollars gold. The country rock is lime and granite. The veins run northeast and southwest, and dip east. The mines are favorably located. There is a natural wagon road up Wood river to the mouth of Warm Spring creek. The altitude is about 5,000 feet. There are no indications of heavy snows, and no traces of snowslides. The first of May last, bunch-grass was a foot high on the south hills.

The valley of Wood river, in the mountains, is from two to ten miles in width, well adapted to the cultivation of cereals and vegetables as far up as the mouth of Warm Spring creek, and for a stock country it is unexcelled. Wood and water are in abundance, and the climate is particularly advantageous for a winter camp.

Warm Spring creek heads against the Smoky, and is as large a stream as Yankee Fork, carrying, at its lowest stage, 2,500 inches of water. On the head of the Smoky, which forms the head of the Boise river, a number of locations were made this season, of gold and galena ores. There has been but little prospecting in that locality, but the indications are favorable for a large belt of gold quartz and silver ores.

The mines on the Upper Wood river are similar in character to those of Middle and Lower Wood river. Although ledges were discovered there previous to this season, little interest was attached to the mines until July last, when the abundance of the ore and the high assays attracted the attention of miners far and near, and many parties outfitted and went in to explore for mines. In all about 75 locations have been made, many of them of great promise.

Last September the prospectors held a meeting, laid off a town called Galena City, and organized a new mining district known as the Wood River district, and elected James Fulton Recorder, who was subsequently appointed a deputy by the Recorder of Alturas county according to the Territorial law. This saved the prospectors many miles of travel to and from Rocky Bar to put their claims on record. The district extends to the Salmon and the Saw Tooth, and embraces about 600 square miles of territory. The mines of Upper Wood River proper are all in the vicinity of Galena City. The belt, so far as developed, is about three miles in length and two in width. It is a network of veins; the croppings prominent and often traceable for thousands of feet. The Wood River ores carry from 40% to 75% lead, and from \$80 to \$300 silver, sometimes much higher than this in silver. Most of the veins bear no trace of gold, but an occasional one is found which shows from \$5 to \$25 per ton.

Galena City is five miles from the dividing waters of the Salmon and Wood rivers, and 12 miles from the Saw Tooth mines. The trail leads over a low divide to the Salmon, over which a wagon road can be constructed with little cost or labor. From these mines to the Warm Spring Creek mines, the distance is about 25 miles, and down to the old emigrant road about 50 miles. There is a natural wagon road up Wood river to within a short distance of Galena City. With its numerous rich mines, and its inexhaustible supplies of limestone, iron and wood, the Wood River country must, in the near future, become a great field for the reduction and shipment of its ore.

About Horse Power.

Horse power is a unit of power established by James Watt to be equivalent to a force of 33,000 pounds acting with a velocity of one foot per minute, which is the same as a force of 550 pounds acting with a velocity of one foot per second. That is to say, one-horse power is 550 foot-pounds of power or effects, or 11-man power of 50 effects each. The product of any force in pounds and its velocity in feet per second, divided by 550, gives the horse power in operation. In Watt's rule for horse power is given a velocity of only one foot per minute, which is equal to 0.2 or one-fifth of an inch per second—about the velocity of a snail. The force corresponding to this velocity is 33,000 pounds, or about 15 tons, which is too large for a clear conception of its magnitude, and a horse can never pull with such a force. A horse can pull 550 pounds with a velocity of one foot per second, which is the most natural expression for horse power. This expression is used on the continent of Europe as follows:

Countries.	Terms.	Units.	Eng. equiv.
English.	Horse power.	550 foot-pounds.	550 ft. lb.
French.	Force de cheval.	75 kilogr. metrs.	542.47 ft. lb.
German.	Pferde kraft.	513 Fuss-funde.	582.25 ft. lb.
Swedish.	Häst-kraft.	600 skapund fot.	542.06 ft. lb.
Russian.	Syl-lochad.	550 Fyt-funt.	550 ft. lb.

SILVER MINE IN OHIO.—Recent news from Ohio relate that lead and silver ore have been discovered on a farm near Cynthiana. Mr. Porterfield, the owner, has sunk a shaft 25 feet, and specimen ore from the bottom assayed 860 pounds of lead and 18½ ounces of silver to the ton.

Fluor-spar in Yolo County.

The *Sacramento Record-Union*, in its issue of November 29th, contains an account of a ledge of fluor-spar found near Winters, in Yolo county. Speaking generally: Spar is a mineralogical term, applied to certain crystallized substances which easily break into cubic or prismatic or other fragments with polished surfaces. There are several varieties of mineral which very closely resemble spar, and it is difficult, without close test, to distinguish some of the agate formations from spar. There is a compound of baryta, the sulphate of which occurs crystalline. Native sulphates of baryta is known as heavy spar. It is found in quantities in Cumberland and Westmoreland, England. Fluor-spar is a mineral product common in Derbyshire, England, and noted for its great beauty. It is generally crystallized in cubes, but its primitive form is octahedron. It is of various colors, often beautifully banded, especially when in nodules, and is much prized for the manufacture of vases, and is occasionally used for heads, brooch stones and other ornamental purposes. Feldspar is harder than spar, and generally light colored. Calcareous spar is white and soft. The beautiful specimen before us we should then class, without chemical analysis or more than test of the eye, as spar of the variety which is hardest, and bears so close a resemblance to agate as to deceive regarding it until its hardness is tested, when it is found to be coarser and more brittle than agate. The specimen was brought to this office by Israel Luce, marble worker. It was found in what is thought to be ledge formation, near Winters, Yolo county, in the same general range with the onyx quarry near Benicia. It is said that a large ledge or quantity of it has been traced at Winters, and that the specimen before us is from the top and presumably not so fine as at greater depth. The specimen has been polished by Mr. Luce and found to work easily, but is of close texture enough and of sufficient strength to bear working up into ordinary forms. It bears a high polish, quite equal to that the best marble will take. It is translucent, and held to the light at a point an inch thick the delicate brown shades of the mineral are shown charmingly blended. The face of the specimen shows a series of handsome meeting arches some three inches span each and composed of alternate bands of black and bluish narrow lines and broad, delicately shaded ones of brown, salmon-colored and tinted as if with burnt umber, brown sienna and finally with a mixture of these and Indian red. Below these arches are rosettes of like shadings. These figures closely resemble the beautiful hand formations found in agate, but exceed them in holdness, size and delicacy of color. This quality of spar, or crystallized rock, would make splendid mantel ornamentation in panels, faces of keystones and supports, etc., and fairly rival onyx. It is probable, too, that it would answer the same purposes accomplished by encaustic tiling, and certainly from the fantastic yet orderly character of the grain and tinting and natural figure work in the spar, would exceed it in beauty. Larger specimens are to be brought to this city and polished and tested.

Cajon Pass Coal Mine.

During the month of February last, a Mr. A. C. Sizemore discovered a coal claim in the Cajon Pass, 18 miles north of Colton, and on the direct line of the Los Angeles and Independence railway as surveyed. Mr. Sizemore was attracted by an outcropping ledge which showed 18 inches of decomposed coal, and could be traced for about three miles in length. Work has been commenced in earnest on the ledge. At last reports the shaft was down a distance of 265 feet, and was still being pushed vigorously ahead. The ledge trends downward at an angle of 45° with the perpendicular. It has well-defined sandstone walls six feet apart, and casings of slate, inside of which the coal appears varying from 18 inches to three feet eight inches in thickness. The strata are said to average about as follows:

Hanging wall of sandstone. Slate casing, 6 inches; coal 12 to 18 inches. Coal and clay mixed of variable thickness. Coal 8 to 10 inches; slate casing 6 inches. Foot walls of sandstone.

The coal near the surface is quite soft, but becomes harder as the depth increases; it also appears to be impregnated with oil, something like cannel coal. It makes a perfect combustion, and leaves a white ash. The mine has been visited by several naturalists and expert coal men, and they one and all pronounced the indications to be those of a true vein. In this respect the ledge is different from any other thus far found in this part of the State.

We understand that Prof. Hilgard has made a critical examination of the coal. It has likewise been put to a practical test by various establishments in our city, and it is pronounced by all to be the best coal ever found in the State. The only question of the success of the mine turns upon the development of a ledge of sufficient thickness to make its working profitable. It is understood that if a continuous vein of four feet is disclosed the mine can be disposed of at a very handsome figure. To put the matter to a thorough test, the owners of the property have extended the time of their agreement with Messrs. Palen & Salesbury six months, and preparations are now being made to enlarge the facilities for work so that the shaft may be continued to a depth of 500 feet.

MECHANICAL PROGRESS.

Rock Drill Carriage.

To ensure the largest possible amount of work done by the drill Mr. James McCalloch, engineer, of Manchester, has invented an apparatus or carriage to be used for supporting or carrying rock-drilling machines for mining, tunneling, and similar operations, and designed to provide an apparatus which will be of great strength, simple in construction and operation, and which will, moreover, afford means whereby the drilling machine may be very quickly and easily adjusted to different positions. By employing an apparatus constructed according to his invention one attendant is enabled to set the machine to work in any desired position and at any angle without loss of time, and with slight exertion. A drilling machine mounted upon this carriage or apparatus may be readily adjusted to the varying height and width of the headings; also to a position for drilling holes at any part and at any angle of the face of the same without removing the carriage from the position in which it is fixed at the commencement of the operations. In carrying the invention into practice he employs an ordinary bogie or truck, which may be on wheels or otherwise; upon this truck he provides a bed-plate, upon which is mounted a vertical tubular bar, which has a screw thread formed upon it. This vertical bar is so arranged that it may be raised and lowered by a screw nut whose outer periphery forms a worm wheel. With this worm wheel is geared a worm fixed upon a horizontal shaft, which may be operated by a crank handle outside the frame of the truck. By this arrangement the vertical bar can be tightened up against the roof to any pressure as may be required, leaving the apparatus in a thorough solid position. Upon the vertical bar he provides a double universal clamp or cross head, which serves to support a horizontal tubular rack bar. This part of the apparatus is arranged to be raised and lowered by means of another screw nut, whose exterior periphery forms a worm wheel, and is geared with a worm fixed on a shaft supported in bearings on the clamp. The rack bar is caused to travel in an horizontal direction by a toothed pinion, which engages with the teeth on the bar, and is operated by a crank or handle at the side of the cross head. The horizontal bar is also moved in a circular direction by means of the clamp or cross head. This rack bar is tubular, and encloses a shaft screwed at one end, its screwed part working into a pivot or end piece for adjusting the bar when in working position. At one end of the shaft there is a self-acting weight, which acts upon the pivot when it is required. By this arrangement the horizontal bar is kept in a constant rigid position while the drill is at work, and at the same time it does not alter the position of the drill from the line of the hole just started. The drilling machine may be mounted upon the horizontal bar, or if required on the vertical bar. It will be readily seen that a rock-drilling machine placed upon an apparatus constructed as above described may be adjusted to any required position or angle without moving the truck whereon the said apparatus is mounted.—*London Mining Journal*.

ANOTHER AUDIPHONE.—The Cincinnati *Gazette* says that Prof. J. W. Graydon, of that city, has invented an audiphone which is claimed to be a great improvement over the Chicago "fan" audiphone. It consists of a small electro-microphone, to the center of the diaphragm of which is attached a cord, which may be of any length, and to the other end of which cord is attached a small piece of wood. The manner of working the instrument is very simple, and can be briefly described as follows: The deaf person takes a firm hold of the piece of wood between his upper and lower teeth, and the party desiring to converse with the deaf talks through the electro-microphone attachment at the other end of the cord, holding the cord taut. The theory advanced is that the sound is conveyed through the nerves of the teeth and the bones of the face to the auditory nerve, which, owing to some defect in the ear, caused by disease, is not approachable through the usual channel, thence to the brain. The instrument will only work, however, when deafness has been caused by disease. In case of paralysis of the auditory nerve it is useless. Some very interesting tests of the audiphone were made at the deaf and dumb department attached to the Third Intermediate school recently. Among others was one, a bright looking little colored girl, who was entirely deaf. The Professor talked to her at a distance of 25 feet through the instrument, and she repeated after him everything which he said. Another was a little girl who had been deaf and dumb from birth. Using the mute alphabet, she informed the teacher in charge that she could hear that one statement of the Professor was made in a louder tone of voice than another, but that she could not understand what he said, never having been able to hear such sounds before.

PHONOGRAPHIC MACHINE.—Sig. Darlo Mazzel, stenographer to the Italian Senate, has invented a machine which claims to produce a speech in the ordinary printed characters as rapidly as it is spoken, a word of several syllables being recorded by a single touch of the keys.

Signals in Mines.

George C. Phillips, of Silver City, Nevada, writing to the *Territorial Enterprise*, of Virginia City, proposes two new plans for signaling in mines. Mr. Phillips says:

Some time since two ideas entered my mind; the first plan is to have a small wire cable extending from top to bottom of the shaft, and at every 400 feet could be placed a small cylinder and piston; a small cord could be extended up 200 feet and down 200 feet from the small cylinder; this small cord could be engaged with a valve or connected with a valve, so as to cause the piston in the small cylinder to pull the main bell rope a certain distance every time. If a small cylinder was placed at every 400 feet each piston could be so engaged to the bell cable as to operate or move the cable a sure and certain distance every time independent of each other, those pistons could be operated by compressed air.

My second plan is to have a three or four-inch pipe or tube extend from top to bottom of the mine, and at every 400 feet this pipe or tube could be enlarged so as to receive a bell, while from this enlarged part a line could be extended up 200 feet and down 200 feet from the bell, and so on until the bottom is reached. The bottom end of the pipe should be closed and a small jet of compressed air admitted near the bottom of the pipe, so as to propel the sound of the bell upwards, and the upper end of the tube should come close to where the engineer has to perform his duty. Either one of those plans will answer the purpose.

You remember my suggestion about entering the smoky mine. Some of my friends say it cannot be done, and ask whether I could go up the smoke stack of a boiler when the stack is full of hot smoke. I intend to demonstrate the whole thing to them soon.

IMPROVED COLLIERY WINDING-GEAR.—A new system of winding-gear, known as Kaeppe's, has been adopted at many of the collieries in Germany and France, and is being introduced at some of the collieries in England. The principal feature in the new system consists in doing away with the ordinary drum and the great weight of rope, which in deep mines is a very great strain upon the engine. In Kaeppe's system the cages are attached to each end of the winding rope, which passes over the head-gear pulleys and over a winding pulley, which takes the place of the drum, and a balance rope of the same weight as the winding-rope is fixed to the bottom of each of the cages, and hangs freely in the shaft, its lower end being allowed to dip into the sump at the bottom. By this method, however deep the shaft, the ropes and cages are always balanced, and the engine in winding up has only to overcome the weight of the rope in the shaft and the friction of the working parts. A steady engine speed is thus secured, whilst considerably less power is required, and the risk of overwinding is very much reduced. The system has answered satisfactorily where it has been tried, and is spoken highly of by mining engineers. Engines and winding apparatus on this principle are at present being constructed at the Bridgewater Foundry, near Manchester, for the Bestwood Coal Company, Nottingham.—*Universal Engineer*.

GLASS TUBING.—The manufacture of glass tubing is surprisingly simple. The glass blower takes a small quantity of melted glass from the pot with his blowing tube, rolls it slightly on a marble slab to give it a cylindrical form, he then adds a small quantity of glass from the same pot and blows the enlarged mass while rolling it, taking great pains to keep the shape cylindrical. If tubes of large caliber are required, the inside diameter of the cylinder is enlarged and the glass is allowed to cool slightly before drawing. For tubes of very small caliber, such as thermometer tubes and other capillary tubes, the internal diameter of the cylinder is decreased and the glass is used very warm. In making a piece of glass tubing, the assistant places a ball of glass against the end of the glass cylinder by aid of his blowing tube. Now the men, each holding an end of the glass cylinder by means of their blowing tubes, begin to separate, walking backward. The cylinder is thus lengthened, and at the same time made smaller in diameter, and the diameter, of course, depends upon how much the tube is drawn out. When the tube has attained the right size, it is generally too warm and soft to admit of laying it down without destroying its shape; it is therefore cooled by means of a fan. When it becomes sufficiently cool, it is laid upon a series of equidistant parallel wooden blocks of uniform height, where it remains until it becomes cold. It is then cut into lengths with a diamond or a file. If the tubes are to resist great pressure or changes of temperature, they are annealed with great care. They are sometimes plunged into boiling linseed oil and slowly cooled.—*Scientific American*.

SLIDE-VALVES.—Improvements in slide-valves for portable, traction, stationary, and other engines, have been recently patented in England, by Messrs. Clayton & Shuttleworth, of Lincoln. These parties construct the slide-valve with two faces placed at an angle—preferably a right-angle—the one to the other, the port face of the cylinder, to which the valve is adapted, being made of an angular recessed shape, to correspond therewith. The joint width of the two combined faces containing the steam ports is of the same superficial area as the valve ordinarily used. The orifice for the

reception of the valve rod is placed at or near the center of the triangle formed by the end of the valve, this point being practically the center of adhesion; hence, the cause which produces the tilting or rolling motion above referred to is removed, and the valve will retain indefinitely a steam-tight force. This improvement is said to remedy the tilting or rolling motion of ordinary slide-valves, which wears the face to a convex form, causing a wasteful escape of steam.

SCIENTIFIC PROGRESS.

The Problem of Solar Radiation.

One of the most stupendous problems staring the modern physicist in the face, is to explain how it is possible that the solar energy, which reaches us in the form of heat, can pass through millions of miles of that space through which the earth is being driven by its momentum, and in which space a most intense cold prevails.

If the earth had no heat of its own, this solar radiation would be incompetent to heat its surface to such a degree as to make organic life possible. This is proved by the perpetual snow on high mountain tops, which lose so much more by radiation than the valleys and plains, that the interior heat of the earth cannot keep them at a temperature above 32° Fah. It is proved by the low temperature prevailing on the surface of the moon, which, being so much smaller than the earth and possessing little or no atmosphere, has long since lost the heat required for organic life. It is also proved by the fact that the mean temperature of the ground is always a little higher than that of the air, and increases with the depth, and finally, the 200 active volcanoes on the earth's surface, with the numberless hot springs, are the most potent proofs that the earth's interior must be very hot, and loses this heat only very gradually.

That this terrestrial heat is, at the present stage of the earth's existence, utterly incapable of developing organic life, is proved by the low temperature prevailing at the poles, where the formation of ice is due to the deficiency of solar heat, while on the mountain tops it is due to the insufficiency of terrestrial heat.

Still, however evident and clear is the action of this terrestrial heat, the transmission of the solar heat through millions of miles of a medium so attenuated as to surpass the best vacuum we can produce in our air pumps, is, at the present condition of our knowledge, an apparently insoluble puzzle, and has become more so since the discovery that heat is merely a mode of motion, and, like light, a mere vibration of material molecules. The question is, how can the motion of that interplanetary medium, which is apparently a mere nothingness, evolve through such enormous distances the stupendous energy on our terrestrial surface, which energy is consumed in the raising of water into clouds, and its return as rain and water-power; it is consumed in raising winds and storms, in evolving vegetable and animal life, in short, in performing all the functions pertaining to a live planet. How is this stupendous energy, or latent motion, transmitted through a mere nothing? That is the question.

A New Piston Packing.

A paper was lately read before the Institution of Engineers' and Ship Builders' of Scotland by John Turnbull, Jr., in which Lockwood's new piston packing was referred to. This packing has a spring ring, designed to press the packing rings outward against the walls of the cylinder, and at the same time to press the rings apart against the flat faces, each motion being independent of the other. In plan, it represents a series of contiguous segments of a circle, and in section a single segment of a circle. It is made of steel wire equal in section all through, and in one piece for any diameter of cylinder, thus rendering it equally elastic at all points. The ends are secured together by means of a double-ended bolt, having a solid washer between; and the bolt is made long enough at both ends for additional washers being put on at any time after the ordinary wear and tear of the cylinder and packing rings requires increased tension on the spring ring. The latter is considerably lighter than both the ordinary cast-iron or the helical coiled spring rings. The packing rings have a continuous cavity round their outer circumference, not so much to reduce the friction as to form a receptacle to retain the lubrication and moisture from the walls of the cylinder. Such an arrangement is especially suited for engines having separate exhaust ports, and whose cylinders are horizontal. The inner edge of each packing ring is made parallel for some distance toward the faces, so that the spring ring can enter easily and without any compression; while by the gradual screwing up of a junk ring, the packing rings are brought closer together, and permitted just to touch each other by their inner edges and not to press unduly. During the operation of screwing up, the packing rings are gradually distended by the points of the spring ring acting on an inclined plane, until it comes upon the protecting flanges, when compression downward begins. After the junk ring is firmly screwed up, a hoop-iron gland may be applied round the packing rings to draw them into the diameter of the cylinder, so as to enable them to enter. The gluts or tongue-pieces are made the whole of the width of the face, so that they

cannot get out. In the discussion which followed, several engineers present gave the results of their experience, which was pronounced to be favorable.

Instantaneous Fuse.

An improved igniter and instantaneous fuse has been introduced by Bickford, the object of which is to provide a cheap and simple means for firing a number of blast-holes simultaneously, in place of the electrical apparatus used exclusively hitherto. The new system was exhibited and tested recently before the Mining Institute of Cornwall. It consists of a little cylindrical case of tin plate, devised so as to contain an ordinary safety fuse at one end, and at the other a set of instantaneous fuses, which may be of any number from 4 to 16, representing the number of holes required to be blasted. Between the end of the safety fuse and the ends of the instantaneous fuses is inserted an explosive disk, the action of which is such that on the communication of fire from the safety fuse, the whole of the instantaneous fuses are immediately ignited. The igniter tested contained eight instantaneous fuses, an average number for ordinary mining, and the simultaneous effect of the ignition was at once seen and considered satisfactory. On commencing to show a second similar set, it was suggested by one of the gentlemen present that detonating caps be attached to the end of the instantaneous fuses, so as to enable the company better to judge of the absolutely instantaneous discharge of the quick fuses. Caps were accordingly attached to the instantaneous fuses, which had been purposely constructed of the proper diameter, as their use has hitherto been most frequently with dynamite. The safety fuse having been ignited as before, one single report caused by the explosion of the eight detonators soon followed, showing that the eight fuses had been ignited and conveyed their fire almost instantaneously.

It was stated that this new fuse had been proved to burn at the rate of 100 feet per second, and there next followed an interesting experiment tending to show what an exceedingly rapid rate of combustion was obtained with this fuse. A length of 60 feet was spread out on the ground and fired by means of the safety fuse at one end. On the fire reaching the instantaneous fuse, the combustion of its whole length immediately followed, scarcely any perceptible time, certainly not a second, being occupied. The fuse burns with a kind of explosion, but with very little violence.

Renewing Burnt Steel.

It is generally believed that steel, when once burnt, is absolutely unfit for any purpose whatever, and it seems a difficult matter to convince people that such is not the case. Messrs. Bauer & Co., of New York city, have for some time been engaged in accumulating proofs to the contrary, and show that with the aid of "steelene," a compound which they prepare, burnt steel may be restored, and that, in fact, overheating of steel and subsequent cooling in steelene offers many advantages in working. We witnessed recently some experiments made with the compounds which prove its efficiency. One end of a steel bar was heated and tempered in the usual way, exhibiting a good fracture, the other end was then burnt, cooled in "steelene," an oily, semi-fluid mixture, heated again to a somewhat lower heat than usual, and then cooled in water. A fracture of the burnt steel showed the open granular fracture which would lead to its immediate condemnation, while the same burnt material, after treatment, had all the characteristics of a steel superior to the metal originally treated. We are assured by a firm whose reputation ranks among the highest in this country, that they found the steel work easier by its application, and that it is less liable to break in hardening. Messrs. Bauer & Co. have commenced an interesting series of experiments looking to the use of ordinary Bessemer rail steel for cutlery, saws, files, etc., by a treatment with "steelene." They have succeeded thus far in obtaining creditable results, having made files, saws and knives which rank well. From better qualities of steel they show excellent specimens of springs, so that the results thus far are very encouraging, and may be considered as strong proofs of the correctness of their method of manipulating steel, strongly at variance as it may appear with accepted notions.—*Iron Age*.

ARTIFICIAL FORMATION OF FELDSPARS.—F. Fouque and A. Mitchell Levy have recently prepared the minerals above mentioned. Nepheline is formed when a mixture of silicic acid, alumina and sodium carbonate, in such proportions that the oxygen of protoxide, sesquioxide and acid are as 1:3:4, are heated together; white silk-like crystals are obtained, which, under the microscope, are seen to be small hexagonal prisms (they are 0.12 min. long and 0.06 min. broad), which accord in every respect with natural crystals of nepheline. If somewhat more silicic acid be taken, like that corresponding to the proportion 1:3:4.3, a completely crystalline mass is obtained, which bears in its optical characters the same resemblance to hexagonal nepheline as chalcodony does to quartz. By melting together one-tenth pyroxene and nine-tenths nepheline a mixture of four different minerals was obtained: nepheline, pale green spinel, garnet in brown-yellow octahedra, and microcline. Leucite was also found in the fused product, and resembled both in form and optical characters the natural mineral.—*Comptes Rendus*.

Mining Share Market.

During the past week the condition of the mining share market has been of an ordinary character. The fluctuations have been of so little moment as to preclude any speculation. The market on this coast will undoubtedly remain in its present weak or rather vacillating condition until the newly-elected Legislature has indicated the direction of its acts towards carrying out the provisions of the new Constitution. The long-continued lull and marked inaction of the mining share business has not been without good results. It has enabled reoperation on the part of those upon whom the fever of speculation had set its seal, and it has developed the stronger and more reliable investments from the weaker. As week after week passes, with very nearly the same results as to condition, the sifting, gleaming operation of dullness has been more apparent. Appearances are strong that there will not be any recession in the market towards a heavy rise. Strikes and rumors of strikes have very little effect, and the general lack of enthusiasm is more than manifest from the few small spurts of the past week.

San Francisco Microscopical Society.

The regular meeting of the San Francisco Microscopical Society was held Thursday evening, December 4th, 1879, an unusual number of members present. The business commenced early, with Vice-President Kinne in the chair. Professor Joseph Le Conte was elected corresponding member, and F. A. Holman, M. D., was proposed for a similar membership of the Faculty. Henry C. Hanks, the first President of the society, was readmitted a resident member, without the usual initiation fee required of new members.

After a brief discussion, it was voted to hold the annual reception of the society on the 19th inst., at Mercantile Library Hall; and Messrs. Hyde, Hanks and Mouser were appointed a committee to make the necessary arrangements.

A very interesting paper was sent in by Melville Attwood, Esq., and read by Vice-President Kinne. Specimens of rock sections accompanied the paper, which were shown and explained by the Secretary. Mr. Attwood's paper was on "The Importance of a Classification of Metaliferous Veins," the substance of which we give in another column.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Syndicate, Dec. 4th, \$12,316.33; Northern Belle, Dec. 1st, \$7,475.34; Northern Belle, Dec. 2d, \$7,601.54; Standard Con. Dec. 1st, \$38,829.61; California, Dec. 2d, \$47,805.02; Con. Virginia, Dec. 2d, \$51,083.96; Navajo, Dec. 8th, \$3,600; Belle Isle, Dec. 8th, \$10,000; Gila, Dec. 5th, \$2,579.10; Navajo, Dec. 8th, \$3,600; Belle Isle, Dec. 8th, \$10,000; Northern Belle, Dec. 6th, \$8,489.05.

"THE CALIFORNIAN."—We have before us the first number of "The Californian, a Western Monthly Magazine," published in this city by the A. Roman Publishing Co. The new magazine is founded by the originator of the *Overland*, and reminds us somewhat of that lamented publication. In style and typographical appearance it is, however, for superior, and the contents have a wider scope and more variety. We have as contributors to the first number, Emma F. Dawson, J. H. Hittell, Charles H. Shinn, Mary Austin, H. N. Clement, E. H. Clough, Richard Edward White, Minnie Booth Phelps, Chas. A. Wetmore, W. C. Morrow, Jr., Edward Sill, Prof. George Davidson, J. W. Gally, Chas. H. Phelps, Sarah E. Anderson, Fred M. Somers, Oscar Weil, D. S. Richardson, and Julia Bugeia. We are promised a magazine thoroughly Western in its character and we hope it will receive liberal and hearty support. If the first number is an indication of the character of its contents for the future, it will speedily take its place among the first-class publications of the country.

THERE is a well-founded suspicion that one of the principal men concerned in the plot against the Czar's life, by the explosion last week, is a returned convict from Siberia.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.
COLORADO No. 2.—*Argus*, Dec. 1: During the past week the 20 stamps in the company's mill have been kept running constantly on good milling ore. Everything in and around the mill is in good condition. The mine is looking as well as usual. Ore is being taken from No. 10 level, and from the lower workings, to supply the mill. The west crosscut will be commenced to-day, to cut the ledge 80 ft north of the slope in the lower tunnel.

AMADOR.
BUITE BASIN.—*Dispatch*, Dec. 6: We are pleased to learn that the energetic proprietors of the Butte Basin mine are now getting control of the water in their mine, and are now lowering it at a very encouraging rate. It was at one time feared they would be compelled to stop work owing to the great inflow of water, but we understand they are lowering it at the rate of about 14 ft every 24 hours.

BUTTE.
RICH MINES.—*Groville Register*, Dec. 6: The old Belcher quartz mine at Mount Hope, five miles above Forbes-town, worked 17 years ago by E. H. Pratt, of this place, and others, and abandoned because it was supposed that the ledge had pinched out, has been reopened by Messrs. Mayberry and Mallard, experienced miners from the state of Nevada, and the result is the finding of a ledge in richness equal to the once celebrated Allison mine of Nevada county. The company has erected upon the mine a substantial mill with eight stamps, which has been running about six weeks. Our informant, who is a gentleman of unquestionable veracity, saw from the mine, for six days' run, a gold brick valued at \$2,000. The company, since commencing operations, has expended in Groville alone for supplies, etc., over \$60,000. This and the Banner mine, at Oregon City, a few miles from this town, worked for nearly 18 years, have, through the superior knowledge of working quartz mines obtained from experience in working the silver mines of Nevada, been reopened with astonishingly rich results. The *Mercury* learns from James Harvey, Chief Engineer, that the property is being fully developed. Thirty-two men are employed. An eight-stamp quartz mill is kept constantly at work day and night. The ore is very rich and the rock is getting better every day. The main shaft is down 64 ft, and will be sunk 150 ft further. Sixty thousand ft of lumber has been ordered for use in timbering the shaft. On the 50 level a tunnel has been run into the mountain a distance of 100 ft, from which a drift has been cut and stowed a distance of 200 ft on the main ledge. Sulphurets of an exceedingly rich nature characterize the rock, and the assayer at the mill is confident that the mine is a bonanza of the first magnitude. The prospects in the Vermilion hydraulic mine, at Forbes-town, purchased by Ourling Bros. & Belden, a year ago, from J. W. Vail, for \$8,000, is yielding fine pay, principally coarse gold. The water to work this mine is raised from the South Fork ditch by a force pump, to Perkins' ravine in Yuba county, to the height of 300 ft. The claim is worked through an open cut, and much difficulty is experienced in keeping the cut open, the bedrock being of a clay nature; the bank, when the ground is saturated with water, slides in and fills up the cut. The hydraulic claim of Sam Davis and John Gudyere, purchased of Sam Vail, is presenting excellent prospects. The hydraulic claims of Cruser & Anderson, Forbes-town ridge, upon which they have been working to open for the last two years, is now in working order, and rich developments may be looked for as soon as they begin to wash.

CALAVERAS.
ANDELS ITENS.—*The Echo*, of the 2d inst., contains the following items of interest: Mining in the vicinity of Vallecito is looking up. There are five gravel mines in active operation on the flat, but as water is scarce at the present time they are piling up the dirt preparatory to washing when the water becomes more plentiful. Mr. Mitchell, who is the owner of one of the mines on the flat, has been to Berkeley, Cal., to have his claims registered at Collierville are said to be paying well. They are among the best paying mines in the county. A quartz lode was recently discovered by a gentleman named Moore, on San Antonio ridge, between Murphys and Sheep Ranch. The vein is about 14 inches in width and pays from \$15 to \$20 per ton. The Cataract mine, which is situated at Echo, near the Stanislaus river, and which has been in litigation for some time, is upon which they have been working to open for the last two years, is now in working order, and rich developments may be looked for as soon as they begin to wash.

LONG STAR.—*Calaveras Chronicle*: A bonanza of surpassing magnitude and richness has lately been discovered in Lone Star mine at West Point. Twenty-three tons of ore, crushed in Carlton's mill, yielded 230 ounces of gold, worth \$175.00 per ounce. That is an aggregate of over \$4,000—a yield of about \$174 per ton. It is very rich rock that produces like that, and that makes it more remarkable is the fact that the ledge is fully seven ft in width.

INOYO.
PATERNON PLACER MINE.—*Independent*, Dec. 6: The Paternon Placer mine, which was completely completed and located at Cherokee, Badger Hill and Chimney Hill, four miles above, received a patent thereto a few days ago. This mine is owned by Joseph Hustler, J. Nankervis, M. Fitzpatrick, the Eureka Lake Company, the Milton Water Company, estate of J. B. Hunter, deceased, and about 30 other persons. The claims include an average of over 300 acres, comprising some of the richest ground on the ridge.

MONO.
NOONDAY.—*Bodie Chronicle*, Dec. 6: The combination shaft is down 536 ft, but no more sinking will be done for the present. The shaft has been driven to one hundred ft placed in position at the 312 level, and the other will be put in at the 612 level. The drift east from crosscut on 312 level is in 250 ft, meeting with strata of quartz and looking very favorable. The drift south, on vein No. 1, 312 level, is in about 200 ft, with a large vein and fine ore, assaying \$300 a ton. The south drift on No. 2 vein is in 160 ft, but here the vein has pinched out and gone to the west. The drift north on vein No. 2 is in 160 ft, showing a large vein of paying quartz and fine-milling ore. The upraise from vein No. 2, 20 ft south of east crosscut, is in 75 ft, the vein being large, and giving good ore. On 212 level they have started a crosscut from the extreme end of south drift in North Noonday. It is now in about 60 ft in a good looking country. The upraise from this shaft is in 125 ft, with a large vein of gold ore. The Noonday mill is about finished and will probably be ready to start up on or about the 15th inst.

JUPITER.—The ore body in south drift No. 2 is two ft wide, a large portion of it being good ore. Assays of samples of ore from the face run from \$62 to \$118 a ton, mostly silver.

MCCLINTOCK.—At the end of the north drift, 310 ft from the face, a crosscut was started west and has been driven 27 ft, cutting two ledges of good looking quartz, which prospects well. The east crosscut from the new shaft has been driven 35 ft, and is now in 133 ft, with favorable prospects for striking a ledge.

CON. PACIFIC.—The whole bottom of the shaft is in broken ledge matter, with some streaks of quartz, which gives an assay.

DETACHE.—Since last report the shaft has been sunk 40 ft, and in that distance passed through two more ledges, both pitching west and equally as promising as depth is attained.

QUEEN BEE.—Crosscutting for the ledge and now in 26 ft from the shaft, and in favorable-looking formation, where it is raised with a large vein of gold ore.

SOUTH NOONDAY.—The new shaft is down 76 ft. During the past week very important developments have been

made in the shaft. The ledge was cut at a depth of 70 ft. It is about 6 in ft wide, dipping to the east at an angle of 60 degrees. Some of the ore has been assayed, giving very satisfactory results.

MARYLAND CON.—In sinking the new shaft a fine ledge of high-grade ore was struck on Thursday. This ledge is 18 inches in width, and increases as the sinking progresses. It has been recorded and is known as the McPherson ledge. It has an easterly dip of 50 degrees.

NEVADA.

DEERBECK MINE.—*Nevada City Transcript*, Dec. 5: The gravel in the Deerbeck mine is now looking better than ever before. About 140 tons per day is being extracted, and during the past three weeks some \$10,000 worth of bullion has been sent west. The gravel all passes through the Cox gravel machine already in operation. Another one of the machines is being put up to work the tailings, and will be put in operation the early part of next week. When the projected tunnel from North Bloomfield is completed, the mine will be immediately on a dividend-paying basis. It is believed that enough pay gravel will be found in putting the tunnel through to offset the expense incurred in its construction.

EAGLE MINE.—*Transcript*, Dec. 6: The Eagle quartz mine (formerly Davenport), on Deer creek, just above this city, owned by Messrs. Byrnes, Hubbard & Co., is being opened up by a force of six or seven men. The drift, at a depth of 70 ft on the incline, is being continued to the north, and is in about 100 ft. The vein is from eight inches to two ft thick, and has some 12 tons of ore on the dump this assays at \$103, and will probably mill in the neighborhood of \$30. This claim was formerly a splendid producer, and the developments since the present owners revived it have been so encouraging that they propose to erect hoisting works on it within a few weeks. The machinery will be run by water at a very reasonable expense.

THE PHOENIX MINE.—Work has been recommenced on the Phoenix (formerly Cummingham) mine, at the east side of Gold flat, and this time evidently in earnest. The workmen are cleaning out the old tunnel and retimbering it, and laying a track. Drifts are to be run on the north and south ore chutes, above the 210 level.

GILLESPIE MINE.—Gillespie & Son, on Gold flat, continue to take good ore from their mine across the road from the Thomas works. It will be remembered that the last crushing paid about \$20 a ton, all specimens having first been picked out and only the low-grade rock put through. This mine has produced some of the richest specimens ever found in Nevada county.

NEW YORK HILL.—*Grass Valley Union*, Dec. 6: Some very rich quartz has been coming out of the Ford & McDonald claim, on New York hill, of late. Some of the pieces are said to be nearly half gold. The ledge, which this quartz is taken from, is small, but this is more than compensated for by its richness. The prospecting shaft on the Irish-American is down 100 ft, and from the fact that the flow of water is increasing it is expected that the ledge, which is being sunk for, will be reached any day.

STRIKE ON GOLD FLAT.—*Transcript*: George Simmons, of the Towle Creek house, has some other parties, have recently made what is described as a very rich strike on Gold flat. They sunk a shaft 30 ft deep, and at that point developed the Green Mountain ledge, which has a westerly course from the school house, and is about two ft thick where tapped. The ore contains much free gold and sulphurets. The windlass, which has been in use thus far, is to be supplanted by a horse-power hoisting apparatus, and work will be carried on by day.

EL CAPITAN MINE.—*Herald*, Dec. 6: The rock in this mine looks well, and the ledge is clearly defined. The ore taken out and crushed thus far in sinking the incline has paid \$10 per ton, besides the sulphurets. A good six-inch pump is in the mine, which will be capable of keeping the mine free from water. The Superintendent has let a contract for sinking the incline down 100 ft further, and when the job is completed, tunnel will be run along the vein and stoping of ore commenced. The El Capitan proper extends 1,000 ft in length along the lode.

TUOLUMNE.

A MINER'S.—*Sonora Independent*, Dec. 6: We learn that Mr. Zimmerman has struck very rich pay in his claim back of his store, on Washington street, which is at the base of the hill on which is located the Divoll & Co. bonanza, where \$265,000 was recently captured. The lady is a host in herself, and manages her own claim. She employs two men in the shaft and attends to the windlass herself.

GLISSEY DISTRICT.—Much excitement exists in the Glissey mining district, and a town site has been laid out. It is also said that 300 men are to be put to work in the Glissey mine; 60 immediately on different parts of the mine, and the balance as soon as it can be sufficiently developed to work them to advantage.

QUARTZ MILLS BURN.—Some three years ago there were but three quartz mills in operation in this county, so depressed was the quartz industry at that time, we can find no record of 100 running and about to run at no distant day, viz.: Confidence, Soulsby, Hunter, Spring Gulch, Morris, New Albany, Riverside, Evans, Tiger, Patterson, Atlas, Harris, Heslep, Seabers, Golden Gate, Nonpareil, Mount Jefferson, Big Creek mill, Little Gorman (Saw-mill flat), Haight (Chile), Keltz, Starr King and Gem.

A good claim—a big "chispa" was found in the Smith & Winkler claim, at Brown's flat, on Friday of last week. The piece weighed 234 ounces and contained 15 ounces of pure gold. In three days the claim yielded five ounces of fine gold besides the chunk, or \$436.

LIONA MINE.—We were shown some rich rock from the Liona mine. The company have now about 25 tons out, which they will crush before taking out more. Should this lot prove satisfactory, tunnel and mill improvements will immediately be erected at the mine.

FRAGSON MINE.—*Union Democrat*, Dec. 6: This week 230 ounces of retorted gold, of the value of about \$3,700, was brought to town, the result of 12 days' crushing. The previous run, of 114 days, yielded \$2,747.78, making a total of nearly \$6,000 for 234 days' run in November. A rich body of ore is developed, and the mine promises to pay largely. Some of the ore is too rich to be worked in a mill.

RODGERS MINE.—Work is being pushed on the Rodgers mine, on Piety hill. The incline is now run 170 ft down. Tuesday it struck into an old drift known as the English tunnel, which has become a reservoir for water sinking from the surface. The water is being raised, which will take a few days, when the incline will be carried on. The ore taken out of the vein prospects well.

NEVADA.

WASHOE DISTRICT.

UNION CON.—*Gold Hill News*, Dec. 10: The drift running east, 10 degrees south, has reached what is supposed to be the east clay of the ore body, and sill floors are being extended along the drift, and it is being timbered up preparatory to extracting the ore which has been laid bare in the drift.

MEXICAN.—The north drift, 2300 level, is cutting heavy clay seams laid in bird's-eye porphyry, and in the clay are stringers of quartz dipping to the east and looking very promising.

CON. VIRGINIA.—Connection had not last evening been made between the south drift, 2150 level, and that north from the bottom of the Joint Best & Belcher winze. It was expected, however, that every blast put in would cause an opening.

CALIFORNIA.—Stoping ore on the 1750 level, and from the drift south from the north winze, has been commenced.

SIERRA NEVADA.—The drift north from the east shaft is being continued through a fine ore formation; total length of drift, 140 ft. The stopes on the 2200 level yield 45 tons of good ore per day.

JUSTICE.—The Ramsdell mill is crushing ore from the mine and running steadily. The returns are sufficiently remunerative to warrant the continuation of the work.

OPHIR.—The southeast drift, on the 2200 level, toward the Hardy vein, is in 57 ft, and passing through vein porphyry carrying streaks of quartz.

GOULD & CURRY.—The Joint Best & Belcher crosscut east on the 1700 level is nearing the perpendicular of the new

G. & C. and B. & B. shaft at the rate of six ft per day. The rock encountered continues to be hard and dry; total length of drift, 1,730 ft from the main north lateral drift, which runs 300 ft east of the Bonner shaft.

JULIA CON.—The winze from the 1800 level is being continued on down through a body of fine quartz; total depth, 172 ft.

BELCHER.—The crosscut east, 2760 level, is now in 75 ft, and without material change, the quartz encountered being of a lively and promising character. The south drift on this level is in 540 ft.

SILVER CROSSING.—Crosscut No. 2, 2200 level, has been pushed steadily forward since last report, Twenty-two ft in quartz the face 140 ft from the main lateral drift. Indications of water having been encountered in crosscut No. 1, it has been discontinued; total length, 138 ft. The tank drift, 2200 level, is in 65 ft.

ALTA.—The last set of timbers above the 1960 level of the incline was placed to-day. Of late, work in this part of the mine has disclosed some very fine quartz and some stringers and bunches of ore. The Lady Washington drift, north, on the 1550 level, is nearing the north line of that mine, and is in fine vein matter.

HALE & NORCROSS.—Crosscut No. 2, 2200 level, is in 00 ft, the face in good vein matter carrying stringers of quartz. Crosscut No. 3, 00 ft from the Chollar line, is in 35 ft, and is in the matter of the vein which looks well.

ST. ANTONIO.—The crosscut east from the main south lateral drift on the 750 level is now over 100 ft, over half of it in the ore vein. Thus far only low-grade ore has been encountered, but something better is expected before the east wall is reached. Other crosscuts at more eligible points further north will be commenced soon.

UNION SHAFT.—The foundations for the pumping engines are copied and ready for the machinery. The large waterwheel of the engine has been received and is being placed. Surface improvements are about completed, and the building enclosing the pumping engine and air compressor has been finished.

SOLID SILVER.—The repairs to the main tunnel are completed in good, substantial style, and yesterday a drift or crosscut east was started near the face of the tunnel to intersect the east ore vein. This will make the second crosscut, and is expected to develop valuable ore at that point.

BELMONT DISTRICT.

BELMONT.—*Courier*, Dec. 6: The latest report from this mine, dated Dec. 1st, says: Last report, on drift north from ore body, between 300 and 400 levels, we struck some very rich ore. We then commenced sinking and found it getting larger every foot we advanced; shall continue same, as I do believe it will open up a large body of ore. The ore body in north part of mine is improving every day, and the ore of a much higher grade, some of it assaying \$2,000 per ton.

ANTONIO MINE.—Mr. Coulter, the Superintendent, in his report of Dec. 3d, says: Since my last report we have crossed the ledge at the bottom of the winze and find it over 10 ft thick at that point. The vein stuff consists of broken up quartz and porphyry mixed with clay. Three assays made last week gave as follows: Decomposed quartz mixed with clay, etc., \$12.66; porous quartz, yellow chlorite, \$13.05; poorest vein matter, \$9.43; average about \$22 per ton in silver. These assays from the ledge several hundred ft north of the ore chute leads me to believe that we will surely find ore, on our 450 level, as much richer than the above assays as the difference is in the same distance on the surface. We have also started a drift northwesterly from the winze, following on a vein of fine chlorite. This drift is now in 15 ft, and the ore improves as the work progresses. When the ore we extract as we run through it is stored in the 300 level.

BRISTOL & POCHE DISTRICT.

ITEM.—*Pocoho Record*, Dec. 6: The furnace which was set up on the 21st of October, was run down for the want of coal on the 1st of December, having turned out during that time bullion in large quantities and working through a large amount of ore. By the time the furnace will be ready to start up, on the 20th, it is expected that in the interval coal will come in sufficient quantities, and with the amount that will continue to come in daily, the furnace will be able to run from 100 to 150 days.

TEM PAHUTE DISTRICT.

ITEMS.—*Tybo Sun*, Dec. 6: The altitude of the mines above the base of the mountain is 300 ft, the average dip of mountain from summit to base is 30°, the face of the mine is north and south, and the east. There are 12 pipes or chimneys of ore showing itself on the surface and different workings of the different mines from the Blue Belle on the north to the Balbec on the south, and all dipping apparently on the strike of the lode or mineral belt to the north and east. There are five pipes or chimneys of ore on the hanging wall from 25 to 300 ft in length, namely: The Balbec, The Balbec, The Balbec, The Balbec, The Balbec. The Silver Peak, Santa Cruz & Co., on the quartzite or footwall there being a body of lime or tap rock on the surface. Present developments justify an output of 300 tons of free milling ore per month.

WHITE PINE DISTRICT.

TREASURE HILL.—*Eureka Sentinel*, Dec. 4: Joe Grun-degger, arrived from Hamilton, yesterday. He reports that mining matters are rather dull around Treasure Hill. Work is progressing in the Eberhardt and Henry tunnels, and Hon. Thos. Wren is also running a tunnel into the Gb Joe, but outside of this little work is being done. He speaks in confident terms, however, of the future of White Pine, and is positive that it will yet take rank among the bullion-producing camps of this coast.

SILVER MINE.—*White Pine News*, Dec. 5: J. T. Jeffers, Superintendent of the Rabbit Hole sulphur mines, informs us that he has about completed arrangements to supply the whole country with refined sulphur. All the Rabbit Hole mines are now consolidated and owned by one company. The company have let a contract to haul 1,500 tons of brimstone from the mines to the railroad at Humboldt House, and are now making the hauls regularly. They expect shortly to be able to deliver from 10 to 12 tons of sulphur daily at the railroad, and will be able to deliver it at a lower price in San Francisco than what it can be imported for. Their intention is to supply the whole Pacific coast with the article, as there is an unlimited supply of it at the mines. Considerable sulphur is used in the manufacture of acids, and there is quite a demand for it for this and other purposes in all parts of the country.

ARIZONA.

GLOBE DISTRICT.—*Star*, Dec. 4: Fifty miners are at work on the Mack Morris. A 10-stamp mill has been bought for the mine and will soon be on the ground. Ninety tons of ore from the Stonewall No. 1 mine, of all classes, milled at the Isabella mill, paid \$56 per ton. The McCormick mine, owned by Mr. Mansfield, is developing finely. In the Stonewall Jackson mine a rich strike was made on the 300 level. The ore shipped by express several hundred pounds of native silver from this level. One five-stamp mill belonging to the Isabella company, running on custom ores of this district, is turning out \$30,000 per month. In the Alice and Southwest Alice late developments place them among our best mines. Developments on the Black Prince show some good ore and great results are expected by the owners.

SANTA RITAS.—It is said that Eastern capitalists are negotiating for a group of mines in the Aztec and Tyn-dall districts, and they have satisfied themselves of the value of the property examined. These gentlemen propose to take a group of 13 mines, make two incorporate companies of them (or more), and set aside one-half of the entire capital stock for sale to the proceeds of which the first development of the mines of the companies, and build reduction works to handle 30 to 50 tons of ore per day. A gentleman who left here a month ago for the East, telegraphs that he can organize a strong company for the Santa Ritas, who now owns a first-class 10-stamp mill, improved roaster, and all the appliances for working ores by the Austin process, and they desire to arrange for active operations early in January.

Important Patent Decision.

The United States District Court for the Northern District of Illinois, has recently rendered a decision which will be of interest to patentees generally. Section 4901 of the Revised Statutes of the United States, title "Patents and Copyrights," declares that: "Every person who in any manner marks upon or affixes to any unpatented article the word 'patent,' or any word importing that the same is patented, for the purpose of deceiving the public, shall be liable, for every such offense, to a penalty of not less than \$100, with costs, one-half of said penalty to go to the person who shall sue for the same, and the other to the use of the United States, to be recovered by suit in any district court of the United States within whose jurisdiction such offense may have been committed."

It appears that the Singer Sewing Machine Company retained the word "patented" on the machines manufactured by them, notwithstanding that all of the patents under which they were formerly made have expired. William G. Wilson, the inventor of the Wilson sewing machine, brought suit against the Singer Company, to test their right to use the word "patented" on their machines. The declaration contained three counts, charging a violation of this statute by putting on 100,000 machines the words "Patented Sept. 10th, 1846; May 8th, 1849; Nov. 3d, 1850; Aug. 4th, 1851; Aug. 12th, 1851; April 11th, 1854; May 30th, 1854; Nov. 21st, 1854; Dec. 19th, 1854; May 29th, 1855; Oct. 9th, 1855." This made 100,000 offenses, which, at \$100 for each offense, would make the neat sum of \$10,000,000, of which one-half was to be given to the informer. A demurrer was filed to the declaration, and argued at some length.

Judge Blodgett, in deciding the matter, declared that the point made by the plaintiff was that "because the Singer patents had expired the company had no longer the right to affix to the machine the word 'patented,' or any word or sign importing that it, or any part of it, was patented or had been patented." The statute was highly penal, and its scope would not be extended by implication. It must also be strictly construed. The law of the United States in force at the date of the several dates inscribed on the machines limited the life of a patent to twenty-one years. That was fourteen years for the original term and seven years' extension, if an extension was granted. It is clear then that at the time when the company was charged with having committed the present offense, the patents mentioned in the inscription had expired by limitation of law, even if all had been extended so as to remain in force the full twenty-one years. The mischief which the statute intended to punish could hardly be stated more concisely than in the words of the law itself, "the purpose of deceiving the public," i. e., stating falsely that an article was then the subject-matter of a patent. Could it be said that the public was deceived by the notice inscribed on or affixed to a manufactured article that it had been patented and that the patent had expired? The "public" was presumed to know the law as well as a patentee—to know that a patent issued on the 9th of October, 1855, had expired on the 1st of November, 1876. If, therefore, the inscription were true, in fact, as it was conceded to have been in the present case, it did not subject the defendant to the penalty of the statute. After a full consideration of the case, the Judge concludes that the plaintiff had not made out a case within the intent of the law. The question at issue involved the merits of the case, and the demurrer must be sustained.

Petroleum Fuel in Iron Furnaces.

A process of using crude petroleum as fuel is employed at the Eames Iron Works, Titusville, Pa. The advantages of petroleum as a fuel are the perfect control under which the heat is held, the extremely high calorific intensity, and the freedom of the fuel from any elements injurious to the iron. It is claimed that the work can be performed much quicker, and the quality of the product can be made more uniform and of higher grade, than can be secured with coal fuel.

The generator wherein the petroleum is vaporized consists of a cast-iron vessel with horizontal shelves projecting alternately from opposite sides, over which shelves the oil, entering overhead by a quarter-inch pipe, trickles down. This generator is contained in a brick setting about six feet square and five feet high. Around and below this is a large iron box called a superheater, the four sides of which are full of flues. Below that again is the furnace, containing another superheater surrounding the fire.

A six-inch oil pipe 75 feet high stands a short distance away. This is sealed at the top, and is pumped full of oil by means of a smaller pipe running up its side. There is also an overflow pipe attached, by means of which the large pipe is relieved when full, the oil returning to a tank built in the ground for that purpose. At the bottom of the great pipe is a small one that leads to the top of the generator, while another pipe runs from the boiler to the bottom of the same vessel and supplies the steam. The 75-foot column of oil yields a uniform pressure of a trifle over 24 pounds, but a steady 20 pound is all that the gauge is required to indicate for the

generator. The column is used in preference to a pump on account of the evenness of its pressure, which never varies in the slightest degree. From this column the generator is fed through a small aperture, the oil trickling down by drops on the different series of shelves mentioned above.

The steam, after leaving the boilers, is passed through the coil of pipes in the superheater until it is heated to incandescence and finds vent in the bottom of the generator, and there meets the oil as it drips from the bottom shelf. Every trace of oil is taken up and swept on to the combustion chamber, where it is ignited and also forced into the furnaces by the air blasts which it encounters at this point. The combustion chamber consists simply of a cellular tier of fire bricks placed on ends, extending across the bridge wall. Within these cells combustion begins; and it is found that if this combustion space has a horizontal thickness of more than 18 inches, the fire bricks fuse down. The heat escaping from the two furnaces passes through the flues of the two 60-horse power boilers, which supply the power for all the heavy machinery in the works. A 12-horse auxiliary boiler furnishes the steam for the generator.—*Oil City Derrick.*

New Caledonia Nickel.

At the present Industrial and Scientific exhibition at Paris, France, a collective exhibit of nickel is made by the *Société Française Anonyme de Nickel*, which company has been formed to work the extensive deposits of nickel ore, discovered by M. Jules Garnier in New Caledonia, and called after him *Garnierite*, by the unanimous consent of Professors Dana and Liversedge, and Mr. W. B. Clarke, the American geologist, who were associated in the discovery. M. Garnier believes this mineral to be contemporaneous with the magnesian rocks which constitute the frame-work or skeleton of the island, and to have been deposited while in solution in the hot and siliceous water, in the numerous clefts of the serpentine. It is here that the ore is found in the greatest purity and in the largest quantities, but it is also met with in the diallage, diorite and amphibolite rocks, which cut up the serpentine into innumerable veins. Though garnierite is generally accompanied by oxides of iron, chromate of iron and black oxide of cobalt, it is distinguished from all other nickel ores that have yet been discovered by being absolutely free from sulphur, arsenic and antimony, which have rendered smelting so difficult an operation. It is a double silicate of nickel and magnesia.

Nickel was formerly extracted from its ore by a long series of complicated operations, embracing both the wet and dry ways; but as, in garnierite, there is no sulphur, arsenic or antimony, and but very little iron or cobalt, only two dry operations are required. The ore is raised by Messrs. John Higginson & Co., from their mines near Numea, and subjected to a preliminary fusion in blast furnaces erected on the spot. It is then shipped by the *Société Française Anonyme* to their works at Septemes, near Marseilles, where it is refined in special furnaces by methods patented by M. Garnier, who has joined the company. The metal is supplied to founders in a perfectly pure state, in the form of ingots and granules, or alloyed with an equal quantity of copper. In this way a perfect guarantee is afforded to purchasers, which is not the case in alloys with an undefined content of nickel. In order to facilitate the introduction of their metal into foreign countries, however, the company undertake to supervise the mixing and casting of white nickel bronze, containing about 20% of pure metal, which is sufficient to prevent oxidation.

The object of the collective exhibit is to show the adaptability of nickel alloys to the various branches of industry, and especially the great advantage of employing nickel bronze, instead of brass nickelized by electro deposit. While the former keeps bright without any special cleaning, the thin nickel coat of the latter soon wears off at projecting edges, and exposes the brass beneath. While being 20% stronger than brass nickelized, nickel bronze costs only 5% more at the low price at which the raw material is sold by the *Société Française Anonyme*; and another point to be noted is that nickel bronze may be worked by exactly the same plant and processes as copper and brass.

The case also contains some specimens of *acier-larocque*, or cast nickel steel, and its industrial applications, exhibited by MM. Rullier, Manget et Cie. This combination is the result of experiments by M. Larocque, who found that a small quantity of nickel (3% to 10%) greatly increases the strength of steel, especially the resistance of a cutting edge, while, at the same time, preventing oxidation. An anvil, hammers, axes, wheels, rolls and parts of machines are exhibited, and show a remarkably fine surface.

A VALUABLE INVENTION.—Weetcheater, South Carolina, has a cotton factory that spins yarn directly from the seed cotton. The machinery is simple, and it is claimed that by its use the value of the staple can be increased nearly 100%, taking into consideration the amount of money saved on bagging, ties, packing, weighing, storing and shipping. The *Atlanta Constitution* predicts that in the course of the next two years at least 100 of these factories will be in operation, in Georgia, as "wherever there is a grist mill, planing mill or saw mill, a yarn factory can be added without an increase of power, and at a very little increase in cost."

The Kane Geyser Well.

A singular freak of nature occurs in the Kane geyser, or Spouting water well, which during the past year has attracted such general attention in Pennsylvania. The cause of the action has been so erroneously represented that a correct explanation seems to be demanded.

This well is situated in the valley of Wilson's Run, near the line of the Philadelphia and Erie railroad, four miles southeast from Kane. It was drilled by Messrs. Gruhout and Taylor, in the spring of 1873, to a total depth of 2,000 feet. No petroleum was found in paying quantities and the casing was drawn and the hole abandoned, since which time it has been throwing periodically—10 to 15 minutes—a column of water and gas to heights varying from 100 to 150 feet.

During the operation of drilling, fresh "water veins" were encountered down to a depth of 364 feet, which was the limit of the casing. At a depth of 1,415 feet a very heavy "gas vein" was struck. This gas was permitted a free escape during the time the drilling was continued to 2,000 feet.

When the well was abandoned, from failure to find oil, and the casing drawn, the fresh water flowed into the well and the conflict between the water and the gas commenced, rendering the well an object of great interest. The water flows into the well on top of the gas, until the pressure of the confined gas becomes greater than the weight of the superincumbent water, when an explosion takes place and a column of water and gas is thrown to a great height. This occurs at present at regular intervals of 13 minutes and the spouting continues for 1 1/2 minutes. On July 31st, Mr. Shearer (aid McKean county) measured two columns, which went to heights respectively of 120 and 128 feet. C. A. Ashburner says: On the evening of August 2d, I measured four columns in succession, and the water was thrown to the following heights: 108, 132, 120 and 138 feet.

The columns are composed of mingled water and gas, the latter being readily ignited. After nightfall the spectacle is grand. The antagonistic elements of fire and water are so promiscuously blended, that each seems to be fighting for the mastery. At one moment the flame is almost entirely extinguished, only to burst forth at the next instant with increased energy and greater brilliancy.

During sunshine the sprays form an artificial rainbow, and in winter the columns become incased in huge transparent ice chimneys. A number of wells in the oil regions have thrown water geysers similar to the Kane well, but none have attracted such attention. As early as 1833 a salt well, drilled in the valley of the Ohio, threw columns of water and gas at intervals of 10 to 12 hours to heights varying from 50 to 100 feet. This well is possibly the first of the "water and gas geyser wells."—*Stowell's Petroleum Reporter.*

Michel's Improved Amalgamator.

In our issue of March 29th, of this year, page 193, we described and illustrated an amalgamator invented by Justin Michel, of Nevada City. We see by the *Nevada Transcript* that the invention has been in use at the Maltman reduction works of that place, and, after testing the apparatus, the proprietor has endorsed it in the following language:

One of the Michel pans has been running almost constantly at my works for the past year, and I have no hesitation in pronouncing it to be the best amalgamator for gold ores on the Pacific coast.—O. MALTMAN, Nevada City, November 24th, 1879.

A *Transcript* reporter has visited the Nevada foundry, where the manufacture of these pans has been commenced on an extensive scale, and he describes the construction in detail, but as we have already done so, a repetition is unnecessary. The *Transcript* adds, however, the following:

Settlers are not required in connection with the Michel pan, which is a great saving of course. With a motor of one-horse power, the rate is from 35 to 37 revolutions a minute, and there is a reducing capacity of over two tons of ore per 24 hours. The rich arsenical sulphuret ore recently produced at the Kenton mine was put through the pan at Maltman's works with perfect success.

One important feature of this pan is that no quicksilver is lost during its operations. The tailings from it have been assayed on various occasions, and found to contain so little free gold that they would not pay for re-working by any known process.

To prove that the introduction of it will enable the working of lower grade ores than can be handled profitably with other methods, one instance in particular can be cited. Sixteen hundred pounds of tailings from a quartz mill in this vicinity were recently put through it and paid at the rate of eight dollars per ton.

THE total sales of public lands to actual settlers for the past five years range about as follows: For 1875-76-77 they reached from 3,500,000 to 4,000,000 acres each; for the year ended June 30th, 1878, 7,166,974 acres, and 8,650,119 acres during the year ending with last June. The totals of the entries under the Homestead and Timber Culture law contrast as follows: For the fiscal year of 1877, 2,698,771 acres; for the fiscal year of 1878, 6,288,799 acres; for the fiscal year 1879, 8,026,685 acres.

Origin of the Colorado Canyons.

Pah-goo, a Ute Indian, relative to George West some of the traditions of his tribe respecting the cataclysm which gave Colorado its present peculiar appearance. Pah-goo calls the Colorado river the Toom-pinto-weep, and says that there is an old river bed fully half a mile deep. His forefathers had a tradition that, long years ago, they had lived near a vast warm lake northeast of the high river; that the country was warm, full of high trees and big deer, and big oxen with white horns; that big fishes and snakes as long as a 100 lodge poles abounded in this lake; that one day all the big oxen began to roar together, and that they raised such a steam from their nostrils the earth reeled and the sun was obscured; that suddenly the lake fell, and continued falling for three moons, and then became so much reduced that they knew it not any more, but that the big lake they found had been drained away to the south, and that its warm waters had cut out through the mountains the present canyon of Green river, and of the high river (the Colorado); and that the old bed in the Toom-pinto-weep is where the lake waters were drained. All the big deer and the oxen with white horns strayed away eastward and perished in the mountains. A big flood soon after the above occurrences formed Grand River canyon, and after this flood came a small race of people who had skin canoes, and who brought seed corn of a small kind, called in Spanish *chiquito mayas*; that these people were almost white, and that they taught the Utes how to make good spears and bows and earthenware; that they built stone houses in the cliffs, and cultivated pumpkins, corn and beans; that they had silver and gold in abundance, and iron tools that they had obtained in the high mountains to the northeast; that afterwards, from the northwest, big red Indians came over to this country and killed and drove off the little people, who finally all went south, as well as the big red men, who are the Apaches, Navajos and Kiowas.

These small and nearly white people were undoubtedly the Aztecs, who certainly wandered in the direction of Colorado, being driven there by the occasional plagues which nearly depopulated northern Mexico centuries ago. Pah-goo declares that "grande lagarios" (probably alligators) were found among the Apache and Navajo Indians, but that they all disappeared as the country became drier and colder. It appears from the traditions that melted rocks were poured out everywhere and left the country desolate. It is, also, of tradition that in the old river bed of the Colorado there is plenty of gold, which fact was related by the Aztecs or small men.

NEW GOLD-SAVING MACHINE.—At the Scadden Flat mill, a new style of gold-saving machine has been set up by the patentee, Mr. Newbury, who is experimenting with the tailings that run away from the sluices below the mill. The machine bears some resemblance to a mammoth smoking pipe, the stem being an upright cast-iron tube, about five inches in diameter, which connects at the bottom with another hollow upright casting, about twelve inches in diameter, which rises alongside of the stem to about one-fifth of its height. Inside of this bowl is an iron framework with both upright and horizontal flanges, which is worked by a ratchet leverage, and is intended to keep the quartz-sand and quicksilver in motion. The machine is charged with six flasks of quicksilver, which amount makes the quicksilver rise to the height of about 15 inches in both the hollow stem and bowl. The quartz tailings are conducted into the stem or column at the top by a funnel, and from the stirring motion given to the quicksilver, by the framework and flanges spoken of, the sand pass down through the quicksilver in the stem and up through that in the bowl and then discharge to waste. It is claimed that by this operation (every particle of sand having to pass through the mass of quicksilver), that the free gold, however infinitesimal in fineness, is saved, and that the sands which escape will not show the least "prospect" in gold. The theory of this invention is not new, but the mechanical operation of it is different from any that has yet been presented. As it is generally admitted that there is quite a percentage of fine gold lost in ordinary milling operations, any invention that gives promise of reducing this loss is worthy of study and trial on the part of those engaged in the business of reducing quartz.—*Grass Valley Union.*

LITTLE over 40 years ago every particle of the table cutlery used in the United States was imported from England. At the present time, out of an annual consumption of \$2,430,700 worth of those commodities, England supplies not more than 8%, and American cutlery now goes largely to Australia, South America, and even to Europe.

THE jury impaneled at the international exhibition of science applied to industry in France, has awarded the diploma of honor to the signal corps of the United States army for the most perfect system of collecting and utilizing meteorological data for the benefit of commerce and navigation.

THE highest inhabited house in the world is said to be the one erected for the miners employed on Mt. Lincoln, in the main range of the Rocky mountains, Park county, Col. It is 14,157 feet above the level of the sea.

The Study of Political Economy.

An eminent English writer in a leading American periodical* holds that political economy is not a science, and argues lucidly in support of his view. Upon this leading point, however, the doctors disagree, and we are willing that they should have the full enjoyment of their discord. We find in the lateral branches of this writer's argument certain statements, definitions and allusions which seem to us of the utmost importance, and we use them as a text upon which to found an exhortation.

In this age of our country, which may, we think, be fitly termed its industrial age, it seems especially desirable that those actively engaged in the development of our industries should put forth extra effort to inform themselves as fully as possible concerning the laws which underlie production and trade. Our understanding of the natural laws and of the material which are involved in our work is advancing most rapidly through the discoveries of scientific investigators and in the light of experience. It cannot be doubted that this branch of our industrial education is progressing faster than is our understanding of the laws which underlie success in production and trade as embodied in political economy. The plain inference is that our minds should be rounded up in this direction, and therefore we commend all our readers who are not familiar with the subject to give a part of the coming winter evenings to the study of political economy. For the young man of sober mind, and possessed of a desire to master some of the world's most practical problems, the study of political economy affords an opportunity for self-culture easily attainable and very satisfactory.

We find in the article alluded to above, the most direct commendation of political economy to the ordinary reader. The writer fitly denounces the style adopted by some economical writers, and which he attributes to their overweening desire to make a "science" of their subject, as though, forsooth, in making their meaning obscure by the adoption of ingenious and uncommon terms, they could elevate the theme to the plane of the exact sciences. As this writer forcibly observes:

"The language of every-day life was cast aside, and that of intellectual casuistry put in its place. Merchants, traders and artisans found matters which occupied their conversation every hour wrapped up in language new, hard and unfamiliar, and this, be it carefully observed, on matters which they felt no want of good and expressive words to discuss. Had they been in search of astronomical or geological information, unusual language would have seemed natural; they would have had the feeling of their own ignorance and of the abstruse nature of the subjects. But to hear buying and selling, talked of in hard words and scientific formulas, could only repel them from listening. They called it jargon. Can anyone after this be surprised that a scientific economist is the one person whom every one turned away from on questions of supreme economical importance?"

But this writer does not stop with the denunciation of those who have succeeded in making economical principles obscure and unintelligible. He gives a most encouraging and truthful definition of what political economy really is, and we commend his words to those who may be prompted to take up the line of inquiry which we have advised. He writes as follows:

"Political economy stops at common observation. Unlike geometry and chemistry, it has no beyond. It does not reveal a single new truth which, in some form or other, was not previously known and acted upon by men possessed of natural sagacity. It examines and takes to pieces common processes which underlie the economical action of all men. It shows what they are—why intelligent men have practiced them as the obviously true and natural course to adopt. It discerns the rules which have governed their action, and it can speak of laws, but so also can the laborer, who knows that a vigorous hoeing will greatly enlarge the crop of turnips. Political economy is not a science, but a body of systematic knowledge, gathered from analyzing common processes which the human race has pursued at all times with greater or less efficiency. Its vocation is to unravel the complications of industry and trade, and to apply the suggestions of common sense and natural sagacity to the processes they employ.

Such, in brief, is the study which all our wide-awake industrialists, who have hitherto neglected it, should make a part of their winter's intellectual work. The facts and the deductions from facts which they will acquire and master will give many of them new insight into the causes which underlie success and failure in the world of industry, and there will be many points gained for guidance in individual affairs. At the same time, too, those who pursue the study conscientiously will find their intellectual powers strengthening and sharpening as they proceed, and the result will be that their fathers will have better sons, their children better fathers, and the State better citizens, both as electors and legislators. And the State has need of such a gain.

*"Is Political Economy a Science?" by Prof. Bonamy Price, in *North American Review* for December.

USEFUL INFORMATION.

Belting.

Upon this subject, so important to mill and machinery men, the Cincinnati *Artisan* has this to say: Among the valuable elements entering into belt depreciation may be mentioned its length, width and thickness, strain, friction or power to transmit tension, proper adjustment and temperature. If the belt is of leather and oak tanned, it will last one-third longer than a chemical tanned. The manner in which belting is laced or joined together makes a great difference in the wear. Having each end of the pieces to be joined cut off true and square, and laced not too tightly, the wear of the belt may be decreased 20% per year. Some of the methods used to prevent a belt slipping on the pulley are detrimental to its wear, among which may be mentioned powdered rosin or pitch, which soon penetrates the leather and rots the belt. Ronghiag the surface by filing is another source of wear. Running a belt too tight on a pulley will generate heat, decompose the oil and organic matter in the belt, and hasten its decay. In having a belt sufficiently tight to convey the power and not slip on the pulleys, or so accurately arranged as to just do the work only, the depreciation on the machine may be decreased 2% a year, and on the belting over 20%. This is further seen when we consider that a three-sixteenth-inch leather belt, three inches wide, has a breaking tension of 2,400 pounds, and an ordinary machine with this size belting can be successfully worked with a permanent tension of 180 pounds. Donhling the tension, whilst it would not break the belt, yet the additional force constantly employed—being an increase of about 1-13 of its breaking tension—is so much useless friction to be overcome, and an additional strain on the entire machine, expended to resist the former and a consequent added element of actual wear.

A belt of unequal thickness will not only run badly, but wear much faster than one of equal thickness throughout. Rubber belts depreciate faster than leather. Frequently a few minutes of quick motion will roll the gum off in such quantities as to entirely destroy the belt. During freezing weather, if moisture finds its way into the seams, or between the different layers of canvas in rubber belts and becomes frozen, the layers soon tear apart and the belt is ruined.

Using leather belts in damp places, or where steam comes in contact with them, materially hastens depreciation; fully 10% faster than when run in a dry place.

PRESERVING BODIES.—Mr. Kreismann, United States Consul-General at Berlin, in his dispatch to the Department of State communicates a description of a newly discovered process for the preservation of dead bodies. The German government has induced the patentee to abandon his patent, and has made public a description of the process. The following extracts are translated from the Berlin newspapers: The dead bodies of human beings and animals, by this process, fully retain their form, color and flexibility for years and may be dissected, while decay and offensive smell are completely prevented. Upon incision, the muscular flesh shows the same appearance as in the case of a fresh dead body. The liquid used is prepared as follows: In 3,000 grammes of boiling water are dissolved 100 grammes of alum, 25 grammes of cooking salt, 12 grammes of saltpetre, 60 grammes of potash and 10 grammes of arsenic acid. When cool it is filtered. To 10 liters of this liquid, 4 liters of glycerine and 1 liter of methylic alcohol are added. The process of embalming is by saturating and impregnating the bodies with it. From 1½ to 5 liters of the liquid are used for a body.

AN EFFECTIVE GLUE.—A very effective glue mixture is said to be employed by Turkish artisans in the nice work of attaching diamonds and other jewels to their metal settings. In the production of this substance the method pursued is to dissolve five or six bits of gum-mastic, each of the size of a large pea, in as much spirits of wine as will suffice to render it liquid; in another vessel as much isinglass—previously softened in water—is dissolved in brandy as will make a two-ounce vial of strong glue, adding two small bits of gum ammoniac, this being rubbed until dissolved. The whole is then mixed with heat, and kept in a vial closely stoppered; when it is to be used, the vial is set in boiling water. This cement resists moisture, and will indissolubly unite two surfaces of polished steel.

BROWN DYE FOR SILK.—Fill a copper or sauce-pan with river water. When it gently boils, put in a quarter of a pound of chipped fustic, two ounces of madder, one ounce of sumac, and half an ounce of cam wood—if not required to be so red, the cam wood may be omitted. These should boil at least from half an hour to two hours, that the ingredients may be well incorporated. The copper must then be cooled down by pouring in cold water. The goods may be then put in, and simmered gently from half an hour to an hour. If this color should appear to want darkening or saddening, it may be done by taking out the goods and adding a small quantity of black dye or a small piece of green copperas. When of a proper color, rinse in three waters and hang up to dry.

Uses of Euphorbia Gum.

The London *Times* says: Some few years since a survey was being carried out in Natal for the Colonial government, during which it was discovered by one of the officers engaged on the work, that when certain plants belonging to the natural order *Euphorbiaceae* were cut with the clearing knives, the gum which exuded from the plants adhered firmly to the blades, and was very difficult to remove. It was, moreover, found that the knives so coated did not rust, and this led to further experiments being made with the view of utilizing the gum as a preservative material. Iron plates were coated with the gum and subjected to immersion in the waters of South Africa, which are stated to be proverbial for their foulness and for the rapidity of the growth of vegetation. The euphorbia in Natal grows in close contiguity to the sea-shore, so that there was ample opportunity for securely testing its value as a protective covering for iron against corrosion and marine growth. The experiments proving perfectly successful, it was then sought to put the discovery into a practical form. To this end the gum was dissolved in a preparation of spirits, and this was found to be a ready means of applying it as a coating for ships' bottoms and for ironwork generally requiring such protection, the spirits evaporating and the gum being left on the surface of the metal. With this preparation experiments were made a few years since by Sir Andrew Clarke, C. B., who had a sheet of iron coated with it and placed in the waters in her Majesty's dockyard at Chatham, where anything immersed becomes rapidly fouled. At the end of two years the sheet of iron was taken out and was found to be quite clean, and free from fouling and corrosion. The composition has also been successfully tested in Africa against the ravages of the white ant. This success is attributed to the circumstance that the gum of the euphorbia, which forms the base of the fluid, is of such an intensely bitter nature that it paralyzes the efforts of all insects to attach themselves to it, or to bore into any substance coated with it. These successes have led to its adoption in practice for the purposes above indicated, and it is now being introduced in England. We have examined several applications of this composition, which gives a glossy coating alike impervious to air or moisture, while, according to results, its own peculiar protective property remains unimpaired.

GOOD HEALTH.

Causes of Insanity.

A table in the last report of the Utica State insane asylum, giving the occupations of the patients, shows that by far the largest number (282 in a total of 410) whose occupation was known were farmers' housekeepers, meaning, we suppose, farmers' wives, laborers and domestic servants. This illustrates that a monotonous and toilsome life, with little or no relaxation or recreation, is more liable to unsettle the mind and destroy the reason than a life of greater mental and social activity. Most of the patients were native Americans, and married. Their ages, in the main, were from 20 to 40; very few were illiterate; but few also had more than a common-school education. In 427 cases but 122 inherited any taint of insanity; 205 patients remained not over six months, and 141 not over two months, showing that the malady was not severe. Intemperance was a minor cause—11%. Female disorders caused about 12%, while the prime cause in the largest number of cases was ill-health, stimulated by overwork, grief, anxiety and sleeplessness. To the causes cited above which encourage mental disturbances, we would add dyspepsia, due to poor or ill-cooked food. In this connection we would refer to the admirable paper on the health of Massachusetts farmers, by Dr. J. F. Adams, of Pittsfield, in the report of the Massachusetts State Board of Health for 1874, in which a large amount of interesting data is given regarding the ill-health of the farmers, and especially of their wives and daughters. Overwork, exposure, poor food, unsanitary dwellings, impure water, unventilated bedrooms and insufficient recreation, are all mentioned as the chief causes of sickness among this class. It is denied that farmers are specially liable to insanity, yet it is added that causes of insanity are not altogether wanting, as shown by the 81 farmers admitted to the asylums the year before. The farmer lives amid more natural conditions than the artisan, business or professional man; but, while he escapes intellectual strain, he labors too incessantly and joylessly, and frets and worries about his crops, his stock and his mortgages. The remedy is more recreation and less work. Then the farmer may lose his reputation for chronic grumbling.

—Sanitary Engineer.

HOW TO OBTAIN SLEEP.—The following is recommended as a cure for sleeplessness: "Wet half a towel, apply it to the back of the neck, pressing it upward to the base of the brain, and fasten the dry half of the towel over so as to prevent the rapid exhalation. The effect is prompt and charming, cooling the brain and inducing calmer, sweeter sleep than any narcotic. Warm water may be used, though most persons prefer cold. To those suffering from over-excitement of the brain, whether the result of brain-work or pressing anxiety, this simple remedy is an especial boon."

Poisoning by Moldy Bread.

That the introduction of fungi into the human system is often attended with fatal results cannot be doubted. Moldy cheese is the delight of certain palates and is the cause of much indigestion, and moldy bread is thus alluded to by the London *Miller*: Some time ago, two persons out of eight who had eaten a portion of a bread pudding in a dining establishment at Bransley, died, and the deaths were naturally the subject of an inquest. Mr. A. H. Allen, a public analyst, testified that he had examined the liver and kidney of one of the victims, and the liver and lungs of the other, without finding any trace of poisonous metal. The material used in making the pudding had been carefully examined with negative results. The glaze of the basin in which the pudding was cooked had been found to be free from lead or other poisonous metals. The pudding had been very carefully examined and no deadly poison had been detected. The negative results of the chemical examinations for various metallic poisons had been borne out by the failure of either pudding to produce purging or other poisonous effects on a puppy which was fed on the suspected pudding for two whole days. There are not a few cases on record of irritant poisoning and death being produced by moldy bread. Thus, horses have been killed in a short space of time after eating such bread in their ordinary food. The symptoms were those of an irritant poison. In 1829, an investigation was made in France into the cause of illaesa due to eating bread, and it was found, by experiment, that bread in a particular state of moldiness or decay may not only produce symptoms of poisoning, but actually cause death; and it was impossible to distinguish the harmless from the dangerous kinds of mold. As fungi grow very rapidly, it is quite possible for moldy bread to be quite poisonous at one date and to have lost its poisonous properties two days afterwards. One of the most poisonous of these fungi is ergot, which produces symptoms very similar to those occasioned by the pudding, and the reports of the evidence in the present case have caused an eminent toxicologist to express a very strong opinion that the presence of this fungus was the cause of the poisoning. The witness stated further, that from experiments and observations he thought it clearly shown that the pudding contained a substance which resembled ergot in all its chemical reactions. The pudding was made of bread said to be moldy, and which was several weeks old and had been in contact with ham, butter and miscellaneous scraps. Mr. Allen then submitted extracts of letters from the leading toxicologists of the kingdom whom he consulted on the subject, and all of whom agreed with him in his opinions as set forth above.

CONCERNING THE MEMORY.—The *Medical Press and Circular* gives some entertaining statistics of memory from M. Delaunay. The inferior races of mankind, such as negroes, the Chinese, etc., have more memory than those of a higher type of civilization. Primitive races which were unacquainted with the art of writing had a wonderful memory, and were for ages in the habit of handing down from one generation to another hymns as voluminous as the Bible. Prompters and professors of declamation know that women have more memory than men. French women will learn a foreign language quicker than their husbands. Youths have more memory than adults. It is well developed in children, attains its maximum about the fourteenth or fifteenth year, and then decreases. Feeble individuals of a lymphatic temperament have more memory than the strong. Students who obtain the prize for memory and recitation chiefly belong to the former class. Parisian students have also less memory than those who come from the provinces. At the *Ecole Normale* and other schools the pupils who have the best memory are not the most intelligent. The memory is more developed among the peasantry than among citizens, and among the clergy than among the laity. The memory remains intact in diseases of the left side of the brain, and is much affected in those of the right, from which it may be inferred that the right side is more the seat of this faculty than the left. From a physiological point of view memory is diminished by over-feeding, by physical exercise, and by education, in this sense, that the illiterate have potentially more memory than those who know how to read and write. We remember, moreover, better in the morning than in the evening, in the summer than in the winter, and better in warm than in cold climates.

VENTILATING BEDROOMS.—A simple device for ventilating bedrooms is within the reach of every one having an ordinary window in his room, by which fresh outer air can be admitted in small quantity with such an upward current as will prevent its being felt as an injurious draft by the inmates. It is particularly adapted to sleeping rooms when the weather is too cold to admit of an open window. Thus, start both top and bottom sashes of the window half an inch, which is not quite enough to clear the rebate or top-heads at top and bottom, but which leaves an opening of an inch between the meeting rails, through which a current enters, but diverted upward by the glass as it should be, so as not to fall directly to the floor, as its coolness might otherwise induce it to do. It thus becomes well mixed with the air of the room without being felt as a draft.—*The Plumber*.

The Week.

The week has been marked by an excellent rainfall and snowstorms, rendering certain an accumulation of water for mining purposes. Active preparations continue to be made toward utilizing the water supply, in the way of repairing and extending ditches and reservoirs. The demand of water will not very much exceed the supply required for extensive mining operations now either well underway or projected by substantial parties.

Missouri has been afflicted with a tornado in Randolph county, which destroyed human lives as well as houses, fences, grain, stock and trees. The most extraordinary occurrence, however, was the singular explosion in Oakland on last Tuesday night. The explosion was caused by an accumulation of gas in the main sewer on Jefferson street. It appears that the gas company have a large gas receiver at the foot of Jefferson street, and the supposition is that at high tide the gas was forced by the water into the branch sewers, and thence into the houses. Along Jefferson street, from Sixth street on the north and Second street on the south, the shock was the heaviest. At No. 306 Jefferson street, the front windows were shattered to atoms. The porch covering the rear portion of the house was knocked completely down, and the baseboards around all sides of the house were scattered in all directions. Inside of the house the mantels were broken, plaster cracked, and things mashed in general. The houses adjoining were similarly affected, but not as much. Between Fourth and Fifth streets, on the same street, the houses, from an outer appearance, looked as though they had been scorched. Those occupying some of the houses were so frightened after the explosion and shake-up, that they would not again retire. This morning hundreds of people flocked to the scene, and every mouth had a theory. Had it not been raining, it is probable that disastrous fires would have occurred. The explosion was simultaneous and accompanied by a sharp report and the tumbling of earth. It is said that the gas was ignited by some person entering an apartment filled with the escaping gas.

[Publishers' Notice.]

Annual Double Sheet Edition "Mining and Scientific Press."

December 20th, 1879.

On the above date we shall issue a Twenty-four page sheet of the PRESS, containing ably and carefully prepared articles on the mining progress of the past year and the outlook for the coming season; on inventions and scientific discoveries; on the advancement and present state of the mechanical arts, trades and home and foreign manufactures.

This opening Nos. of several important series of articles on mining and metallurgy will appear, with contributions from some of our best writers.

A large number of extra copies will be printed and mailed, postpaid, direct to representative miners, mechanics and to leading business and professional men and manufacturers, in San Francisco and throughout the Pacific States and Territories. The issue will be well illustrated, handsomely printed, and we trust prove a credit to the special industries it represents on the Pacific slope. Agents, news dealers and others desiring extra copies should send in their orders as early as practicable.

DEWEY & CO., Publishers.

November 28th, 1879.

German Metallurgists.

It is worthy of remark that Germany, the cradle of mining and metallurgical skill and science, by reason of her immense progressive strides, retains her prominence, and is to-day the home of that science needed in the advancement of this branch of industry.

If we study closely the cause of the success of German metallurgists, we will learn that it is owing to several advantages they possess, which are the result of many years' experience, associated with science and natural advantages. Although Karsten says "that the date of the commencement of mining in Saxony is not to be ascertained, nor is it to be determined where it first began; that we only know with certainty that silver ore was mined in Saxony in the second half of the twelfth century, and reached a prosperous height, through the immigration of Hartz's miners, toward the end of that century." He says also "that the people who overturned the Roman Empire wandered to and settled in Bohemia, Moravia and Saxony in the seventh century, taking with them the art of prospecting for ore and the extraction of metals."

As mining in the Hartz dates from the ninth century, it is in all probability not so old as in Saxony. There is little or nothing extant from which we can discover the exact manner in which the mining and reducing operations were then conducted. Stella informs us "that in the first book on mining laws, which was written in Italy in the thirteenth century, there appeared numerous German technical phrases," which indicates that mining had then its principal seat in Germany. Agricola (1546) describes lead, silver and copper extracting processes which were conducted in a rude manner. We see that mining here has not so ancient an origin as in some other countries; but has been prosecuted with an almost untiring zeal and an energy well worthy of imitation.

This industry has been and is, fostered and protected by the different governments, not only through laws, subsidies and loans, but also by establishing and supporting educational institutions which are directly under governmental control.

True science and industry have been encouraged. By means of these well-regulated mining schools and academies a constant supply is maintained of educated men, who have been directly the cause of Germany retaining her position, and leading other nations with her many valuable improvements.

GOLD MINING IN CANADA.—A correspondent of the Quebec Chronicle writes as follows: The township of St. George, Beauce, presents an appearance never before witnessed in this province. The Sir William Logan estate on Jersey Point, at the junction of the Riviere du Loup and the Chaudiere, is a scene of activity that promises well for the whole district; 120 men and 20 teams have been at work there for the last fortnight under the superintendence of an able mining engineer, and large machinery necessary for the operations has left here by the Quebec boat, which will astonish the population at the mines; they having been satisfied for years to pick up the gold out of the rivers whilst at low water. Other parts of the country are also making a stir, and gold is found and sold daily in various parts.

Classification of Smelting Ores.

At no other metallurgical establishment in the world are to be found so many and various ores for treatment as at the Royal Saxon Metallurgical Works in Freiberg. Almost all known metals are to be found in the ores there treated. The metallurgical processes of Freiberg have for their main object the production of silver, gold, lead, bismuth, zinc, copper, vitriol, etc. In addition to the ores delivered by the Saxon mines in and about Freiberg, foreign and domestic ores are purchased and treated, and also sweeping, or dross, containing silver, lead, copper or gold. This sulphur present, in large quantities in the greater part of these ores, is made use of as much as possible for the manufacture of sulphuric acid; some of the ores carry also a large percentage of arsenic. This is also treated to advantage in the manufacture of various arsenical products, such as arsenious acid, orpiment and metallic arsenic. The silver in the Freiberg ores is more or less finely distributed throughout the ore in the form of silver-glance, staphanite, tetrahedrite, polybasite and native silver. The lead occurs almost exclusively as galena. The copper occurs as copper pyrites, tetrahedrite, variegated copper ore and copper-glance. The greater part of the ores contain, beside these metals, unpayable quantities of gold, bismuth, cobalt and nickel. The gangue is composed principally of calcite, hartspar, fluorite, barite and quartz.

All the ores delivered at the smelting works are divided into two classes—payable and non-payable. To the first class belong all those which contain over a specified amount of metal, and to the second class all those which do not reach this amount. To the non-paying ores belong: Dry silver ores containing from .01% to .04%; copper ores not containing 4% of silver and copper together; lead ores not carrying more than 15% of lead; and nickel and cobalt ores.

All the ores are classified, according to their composition, into nine classes, which are enumerated by Mr. H. Painter, one of the U. S. Commissioners to the Vienna exhibition, as follows: 1, lead ores—*a*, plumbiferous ores, *b*, galenas; 2, copper ores; 3, arseniferous ores; 4, zinc ores; 5, sulphur ores; 6, pyritous silver ores; 7, quartzose pyritous ores; 8, quartzose dry silver ores; 9, spathic dry silver ores. The lead ores are all argentiferous, and comprise about half of the ores delivered at the works. They are classified into plumbiferous ores and galenas. Those containing between 15% and 20% lead belong to the first class, and those containing over 30% lead are reckoned in the second class (galenas). The average percentage of lead contained in all the plumbiferous and galena ores amounts to 40%, and the silver to 15% = 43 ozs., 33 dwts., 14.40 grs. The copper ores are almost always argentiferous, and contain from 1% to 10% copper, with a general average of 3% at the highest.

The delivery of copper ores from the Freiberg mines is, comparatively speaking, very small, but at times rich foreign ores are bought. The arsenical ores contain from 10% to 40% arsenic, viz: *a*, arsenical ores averaging 35% arsenic; *b*, arsenical pyrites, averaging 15% arsenic and 25% sulphur; *c*, arsenical lead ores, averaging 13% arsenic and 18% to 20% lead. They are delivered over to the arsenical works.

The zinc ores, principally composed of zinc-blende, contain from 30 to 40% zinc. Lead ores carrying less than 30% zinc are classed with the plumbiferous ores, and are turned over to the zinc works for treatment. All the zinc ores carry more or less silver. All Freiberg ores that contain 20% and more of sulphur are classed with sulphur ores. Pyritous silver ores are such as are rich in silver and sulphur, and when they contain .20% silver and more the sulphur is not paid for. They do not contain more than 1% copper, or 15% zinc.

The quartzose silver ores are poor in silver and carry a very large percentage of silicic acid. By dry ores, in general, is understood all such argentiferous ores as do not contain lead and copper in payable amounts. By quartzose dry silver ores is to be understood all such as are principally composed of quartz, and contain only so much pyrites that they are not capable of producing 20% of raw matte by smelting. The spathic dry silver ores are only distinguishable from the quartzose therein by the associated gangue, being of a spathic instead of silicious native. The classification of ores may be simplified as follows:

1. Lead ores—*a*, plumbiferous ores, with 15% to 29% lead; *b*, galena, with more than 30% lead.
2. Pyrites, chiefly iron pyrites, containing not more than 15% zinc and very little arsenic.
3. Pyritiferous ores, with 15% to 30% zinc.
4. Blende, with more than 30% zinc.
5. Arsenical ores, averaging 35% of arsenic.
6. Arsenical pyrites, with 18% arsenic and 26% to 28% sulphur.
7. Arsenical lead ores, with 12% arsenic and 18% to 20% lead.

The ores are also divided into stamped, jigged and washed ores, corresponding to the manner in which they are dressed at the mine. Taken as a whole, they are called "elime" ores. The distinction of "lump ore" is also made; meaning ore in pieces about the size of a walnut.

SIR WILLIAM BOXALL, the eminent English painter, is dead.

The Mining Industry and the U. S. Geological Survey.

Now that the different geological surveys are consolidated under one head, with Clarence King in charge, the predilection of that gentleman in favor of practical mining matters will cause more attention to be paid to metallurgical processes, etc., than heretofore. The different surveys have done excellent work in their departments—work appreciated at home and abroad; but as far as the mining industry is concerned, the results have been only general in their nature and related more to general geology than to details of mining matters.

A main object of this United States Geological Survey is to advance the knowledge and practice of the mining arts, by investigation and description of the occurrences of ores, of the methods employed in mining them, and of the processes by which they are treated. We are assured that now every mining district will receive the attention of the survey. The information obtained and the results of special investigations, will be so presented as to afford a trustworthy record of the mineral character of the country and of its resources, and of the methods of manipulation which have proved most suitable under varying local conditions. Each district will therefore receive the benefit, not only of the survey within its limits, but of the collective experience of the whole country. Among other things, the U. S. Geological Survey has been intrusted with the task of gathering statistics for the next census. Raphael Pumpelly is Chief of the Division of Mining Geology, and expert special agent of the census, which is sufficient indication that complete and valuable statistics will be compiled. It is presumed that a list of the quartz mills, roasting and smelting furnaces, quicksilver reduction works, etc., will be made up, and such other information as will be useful to all connected with the mining industry.

Prof. G. F. Becker, formerly of the University of California, is geologist in charge of the San Francisco office, and he is already pursuing the task of collecting mining information for the Survey Reports. Full descriptions of our various metallurgical processes, with the appliances connected with them, is sadly needed; but until now all hopes of getting such information, officially, has been abandoned since our State Geological Survey came to an untimely end.

Altogether, we feel certain that the proposed work of the United States Geological Survey will be of great practical use to the mining community. It is only hoped that the publications will be distributed more liberally than has heretofore been the case with the Government reports relating to mining matters.

AUSTRALIAN GOLD MINES.—Reports from the several mining districts in the colony of Victoria give very encouraging accounts of operations there. The improved prospects of some of the large gold-bearing mines of Sandhurst have given renewed hopes to the miners, mine owners and business people of the district. A striking instance of the good luck which occasionally falls to individual miners was shown in the month of September in the case of four men who were working the St. Mungo claim, Sandhurst, and paying the owners of the mine a certain percentage on the gold obtained for the use of the mine. These men, in a drive at a distance of about 60 feet from the surface, came upon a rich spur of quartz, from the first ton of which they obtained the extraordinary result of 255 ounces of gold. Two loads crushed shortly afterwards gave 191 ounces, and 10 tons from a lower level yielded 50 ounces, making altogether 496 ounces of gold from 13 tons of quartz. Out of that the fortunate four divided £1,400, beside paying £500 tribute to the proprietors of the mine. A week later they had another surprising yield of 255 ounces of gold from two tons of quartz, and an equal quantity of debris from the floor of the drive. At the alluvial diggings at the Whipstick, a place near Sandhurst, a nugget of gold weighing 40 ounces was found by a lucky digger six inches below the surface of the ground. The finder, for obvious reasons, declined to state the locality where he obtained the nugget.

CORNSTALK AND SORGHUM SUGARS.—According to all reports, the sorghum sugar interest of the prairie States is wheeling ahead in a most lively manner. The Commissioner of Agriculture states that the making of sugar from the juice of the amher cane is a complete success. At a sugar manufactory 50 miles north from Chicago, the Commissioner reports a shipment of a carload of most excellent sugar, October 23d, with other carloads to follow. More than this, the Commissioner is enthusiastic over his cornstalk sugar experiments, and promises that with sorghum and stalks the "great West" will soon be flooding the saccharine markets of the world. We hope so.

THERE are now 25 soldiers and 25 Apache scouts at Fort Cummings, New Mexico. The road to the Mimbres is being constantly patrolled, and no party of hostiles could pass up from the south without being discovered.

Immense Mining Machinery.

The Pumping Engine for the Sierra Nevada, Mexican and Union Shaft.

Prescott, Scott & Co., of the Union Iron Works, have just completed ready for shipment another one of the elaborate and massive pieces of mining machinery for which this firm are becoming famous. This is the new pumping engine for the joint shaft of the Sierra Nevada, Mexican and Union mining companies, on the Csmstock. The engine is of a unique type, and the first one of the kind ever built on this coast. The details are from designs by Wm. H. Patton, consulting engineer for the companies mentioned. An idea of the magnitude of the machinery will be gained from the statement that it weighs in the aggregate about 1,200 tons.

It is a direct acting compound hoisting engine, and the two cylinders are upright, and placed at an incline towards each other. The initial cylinder is 65 inches in diameter, with 6 foot 9 inch stroke; and the other cylinder is 100 inches in diameter, by 8 foot 3 inch stroke. The jackets are cast in sections; the liners in one piece. The largest pumping engines on the Csmstock before this were: That on the Chollar-Norcross-Savage shaft, the cylinders of which were respectively 32 and 65 inches in diameter and 10 foot stroke; and that of the Yellow Jacket with cylinders 33 and 65 inches in diameter and 12 foot stroke. The smaller of the cylinders of this engine is as large as the largest of the others.

The larger of these cylinders weighs alone 43 tons, and the smaller one 30 tons. The sole plates for the cylinders weigh 23 tons each. The pistons are 16 inches thick. The piston rods are of different lengths fitted with glands with adjustable gearing and lantern brasses. The engine will run about eight strokes a minute.

The engine sets 18 feet between centers, and is fitted with Eugene O'Neill's improved valve motion, all the valve gear coming in between the cylinders in a very compact form.

The initial valve chest is placed between the cylinders down close to the base, on the side where the engineer stands, and serves to join the cylinders at the bottom. The expansion steam chest is placed on the opposite side at the top of the cylinders. The connection from throttle leads across the top and down the opposite side of cylinders to where the engineer stands.

The fly-wheel sets back of the engine, and revolves on a shaft 27-inches in diameter. This fly-wheel is an immense piece of construction in itself, weighing 110 tons. It is 37½ feet in diameter, and was cast in 12 sections. The center or hub of this wheel alone weighs 15 tons, and pillow blocks 5 tons each. The fly-wheel shaft is connected with two wrought-iron cranks. The engine crank is 6 feet between centers and weighs 9 tons. On the opposite end of the shaft is the crank for the air pump and condenser. This is 3 feet between centers and weighs 6 tons. The connection from the main engine crank to the pump bar or beam is by an immense rod 24 feet between centers.

This big pump bar or beam works in a deep pit or chamber dug out of the ground and is below the engines. The center of the beam is 21 feet 6 inches below the foundation of the engine.

The pump bar is made in sections, of armor plate, flanged and ribbed for strength. The castings connected with the beam to hold the truss, weigh, on each side, 10 tons. The beam is 48 feet between centers, with a double truss running clear around it. The shaft on which this beam oscillates is 22 inches in diameter. The sole plates for the journals of the pump bar are 17 feet long, 28 inches wide and 6 inches thick. The pillow blocks are 18 inches diameter in bore and 28 inches long.

The initial cylinder piston rod link takes hold of the beam at the end where the pump rod is connected, and the link of the other rod at the other end. The bar is journaled a little at one side of the center on account of the preponderance of weight at one end, which accounts for the difference in length of stroke of the two cylinders working at opposite ends of the same beam. The slides of the engine are connected to the coping stone in the pit by immense bolts built in the stone. The link connections from cross-heads to beam are 13 feet 3 inches between centers.

The air pump and condenser are on the right hand side of the engine in a vertical position. The air pump is 4 feet 6 inches in diameter, 6-foot stroke. The condenser is 4 feet 9 inches in diameter. The exhaust pipe from condenser to engine is 20 inches. The condensers and air pump are so constructed as to have a cast-iron casing all around, water-sealed, so when in position they are completely covered up. This casing is 14 feet 5 inches high by 13 feet 6½ inches long, and 6 feet 6½ inches wide.

The connection from the bar to pump rod is by two immense wrought-iron straps, gibs and keys. It is intended to handle a line of pumps 3,000 feet.

The pump rod is made of timbers 13 inches square, with 40 pieces of strap plates, each 33 feet long, 10 inches wide and 1 inch thick, bolted with 1½-inch bolts.

There are six balance bobs on the shaft, placed 200 feet apart and arranged to handle 14 14-inch

plunger pumps and a 20-inch lift pump at the bottom. This sump pump is 24 feet long. The column pipe to the lift pump is 22 inches in diameter, made of lap-welded tube, and is the largest ever manufactured for pump use. To run this engine there are four 54-inch boilers, 16 feet long.

Arizona—No. 6.

[Written for the Press by W. H. S.]

Lucky Cuss Hill, Tombstone District.

Lucky Cuss Hill, where the famous mine of the same name is situated, is about a mile and a half from the thriving town of Tombstone, in a westerly direction, and is the center of a group of rich mines and mining prospects. The Lucky Cuss mine, from which the hill derives its name, is situated on one of its northern spurs, and has five shafts sunk. No. 2, the deepest one, is down 230 feet. One tunnel has been run into the hill about 200 feet, and four or five drifts run on the different levels, of an aggregate length of four or five hundred feet.

This company has some seven or eight hundred tons of ore on the dump, rich in chloride, carbonate and horn silver. The company is erecting a 15-stamp mill at Charleston, about

ten miles west from the mine on the San Pedro river, where they get plenty of water. The mill is to be called the Corbin mill, after the efficient manager of this property, who brings with him to this enterprise a large and successful Eastern business experience. The location of the mill at this distance from the mine, as in case of the Gird and Contention mills, is for the purpose of getting an adequate supply of water, which cannot be done at the mines with their present facilities.

Attention and showing more or less development, may be mentioned the Telephone and C. O. D., owned by J. Murray Bailey, both in rich ore with a promising future. The Grand Dipper has a shaft down 60 feet, disclosing a body of high-grade ore, rich in chlorides and horn silver. The popular Sheriff of Pima county, Shilbell, is one of the lucky owners in this bonanza. The Sunset, recently located by B. Frank Hall, of Philadelphia, has a shaft of 14 feet in rich ore, and the Mizzen Top, owned by Postmaster Harwood of Tombstone, has a 20-foot shaft showing a fine body of ore. The Prompter, owned by Col. Lewis of the Richmond water works, although, strictly speaking, not on this hill, as it lies across a ravine, is deserving of notice from the strong character of its croppings and the great width of its ledge, which is from 10 to 20 feet in porphyritic walls. Two shafts have been sunk, one 25 the other 15 feet, both in the ore body the full width of the shafts, showing chlorides and black sulphurets of silver. The ore assays high and there seems to be plenty of it. The new city of Tombstone, its rapid growth and representative business men, and the other important mining interests centering there, will be commented upon in future articles. The group of mines about the Lucky Cuss are now touched upon because they have been more particularly examined. The map or sketch will sufficiently indicate the location of these mines with refer-

This mine lies just over the hill from the Lucky Cuss, and has a ledge eight feet in width at the shaft. Very rich in chlorides and horn silver. The horn silver, in some specimens, is very handsome, appearing in small bunches or clusters, resembling somewhat fine wire or spun silver. Much brown spar is found, discolored by iron stains. This carries gold as high as \$12 per ton. The assays which have been made from this mine run from \$125 to \$1,000 per ton. The direction of the ledge is about southeast and northwest. The vein has a dip of 80° north, and is in porphyry walls capped in line. Mr. John Haley, of Tombstone, was the discoverer and locator of this mine. He is an old prospector and miner, and knows a good thing in that line when he sees it. S. M. Allis, Esq., Deputy Mineral Surveyor of Tucson, is associated with Mr. Haley in the ownership of this property, including the Allis and Last Chance, which seem to be a prolongation of the Anchor ledge.

Anchor Mine.

Among the other mines of this group, attract-

ence to each other. The mountains of southern Arizona are full of rich mineral deposits and the principal want now is, men of capital to convert these deposits into hullaion. Of men without money, there are enough here already until further developments are made and more machinery put at work.

MANNA IN WASHINGTON TERRITORY.—This is not the manna upon which the Israelites fed in the wilderness, but a substance valuable to the pharmacist and sometimes called fir sugar. It is a cream-colored flaky substance with a sweetish taste, containing mannite, which has a mild laxative effect upon the system. It is the concreted juice of a tree, and the supply now comes wholly from Sicily, being derived from a small native tree, *Fraxinus ornus*. A sample of manna was lately sent from Yakima, W. T., to the Smithsonian Institution at Washington, and referred to the Department of Agriculture for analysis. It is reported to be an excellent article. It occurs as an exudation upon the branches of a species of fir tree and is said to be in such quantities as to break down the branches. It will also doubtless break down the manna market unless some enterprising man should start a manna pill factory or a manna cake bakery. We will accept a royalty of one per cent. on the profits as a recompense for this suggestion.

The Ethiopia, from New York November 22d for Glasgow, and the bark Geffon, from Hamburg for Philadelphia, have been damaged by collision, the former in the Clyde and the latter at Cruhaven,

Threading the Continent.

The return of the sunshine of prosperity to Eastern fields and manufacturing interests is calling capital from its hibernation and warming it up for a season of activity and enterprise which we trust may be long and satisfactory. The era of magnificent enterprises which followed the war bids fair to be eclipsed by the decade which will soon open. There is reason to believe that this will be the case, because the era which culminated in 1873 was one of great inflation and grand ideas, which were but partially borne out by the logic of facts. Hence the decline and fall. We seem now to be entering a period in which sounder views will prevail; in which courage will be duly tempered with caution; in which there will be liberal expenditure no doubt, but upon a better basis of practicality and durability.

The latest advices from the eastern financial centers bring news of unusual activity in railroad enterprises. It is true that there is noticeable a most grasping spirit of monopoly, and most eager efforts to turn the tide of prosperity into certain channels for the aggrandizement of the few, but these endeavors are met by counter movements which bid fair to guard the public interest and turn the designs into schemes which will benefit the whole country. This is the present aspect of the several railroad enterprises which are now racing across the continent. Jay Gould who is reported to have done his best to control the possible approaches to our coast from the East, is now said to have been met and beaten by the Atchison, Topeka and Santa Fe corporation. This company now claims to have secured three approaches to the Pacific coast—one a new line along the 35th parallel due west to Los Angeles, and thence north to San Francisco; another to connect with the present Southern Pacific road, and another to disport into Mexico and strike the Pacific ocean at Guaymas. This is the present announcement of the matter, and work is said to be underway toward such results. Certainly there has never been a time when enterprises seemed easier to prosecute, and there is no lack of capital to carry them into effect. Then, to the north of the existing road, there is the old-time Northern Pacific enterprise, being infused with new life by the return of prosperity, and by the astonishing development of the agricultural interest along our northern boundary.

The question arises whether all these enterprises can prove enduring, and whether they are called for by the growth of the country. It seems clear enough that they are all more feasible than the existing line appeared at its inception. Each of the proposed lines has a far better show of developing local traffic and fostering the growth of the great interior of the continent. For it is fast being demonstrated that the great interior States and Territories are not nearly so worthless as they were once supposed. Agriculture is gaining a permanent hold upon areas which have been regarded as deserts, and mineral resources are being developed where the rocks were counted worthless. This changed view of the vast interior which is forced upon the outside world by the growth of the new States and Territories, is enlisting abundant capital in threading them with new avenues of transportation, and the result is that the country is advancing so rapidly that all former estimates of our national wealth and productive area must be revised and extended. Two or three years ago the man who foretold the present tendency of affairs would have been laughed at as a visionary, for it was then thought that the improvements had so outgrown the demand for them, that it would require a generation to heal the breach. It is a gratifying thought for the close of the decade that the fact seems far otherwise.

The grand producing interests of California must be greatly stimulated by the new lines of transportation to Eastern markets which are now promised. It seems indisputable that between the several enterprises there will prevail a spirit of wholesome competition which will reduce the cost of carriage to a fair figure and thus will incite the development of industries in this State which now are unprofitable. There will also be a considerable reduction of time occupied in transit, which will be a great item in the movement of our perishable products. The approach of through lines to the different parts of the State, should make our growth more symmetrical and encourage many whose present distance from centers is very depressing.

There seems every reason to look hopefully upon the new movements. The relation of railroads to the people is becoming better defined and understood, and the introduction of a "live and let-live principle" seems assured. The force of competition which will creep into the situation and the regulative action which we must hope our new railway commission will exert certainly should give us confidence for the future. It does not appear that any of the coming enterprises propose to place burdens upon the people, except such as may be voluntarily assumed; and if this be their plan, and their work be to draw California still more closely into the sisterhood of States, and her peerless products nearer to the markets which await them, surely we can all speed their progress and welcome their approach.

DE LESSEPS, of the Isthmus canal scheme has sailed from France to Aspinwall,

Scientific and Practical Books
on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by **DEWEY & CO.,** MINING AND SCIENTIFIC PRESS Office, S. F.

BY **GUIDO KUSTEL,**

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the
Extraction of their respective Metals without Quick-
silver. 1870.
This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including
the Chlorination Process for Gold-bearing Sulphurets,
Arseniurets, and Gold and Silver Ores generally, with
120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

The Explorers', Miners' and
Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy,

Containing 672 Pages and 83 Engravings

BY **J. S. PHILLIPS, M. E.,**

Of California, a Practical Operator for Thirty-eight Years; Explorer, and Resident in the Pacific States and Territories for the past Twelve Years.
PRICE—bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS Office, by **DEWEY & CO.**

TO APPEAR SHORTLY.

Grimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. 8vo. Illustrated. By **ROBERT GRIMSHAW.**

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small Hand, Sash, Mulay, Jig, Drag, Circular, Cylinder and Band Saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, \$1.50. Orders for first edition received now.

SECURE PATENTS

Through **Scientific Press** Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. **DEWEY & CO., PATENT AGENTS.**

New Hotel just opened on the European Plan.

ST. GEORGE HOTEL,

812 Kearny St., near Old City Hall.

Meals served in first-class hotel style, of great variety and good quality, at all hours of the day for 25 cents. Steak and coffee, 15 cents; coffee and cake, 10 cents.

Rooms from 25 cts. to \$1 per night, as per size and location.

Board (per week) \$4.00

Room and Board (per week) \$5.50 to \$7.00

Accommodations for families correspondingly low.

North Beach and Mission street cars pass the door.

TIMOTHY SARGENT, Manager.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address **EXPERT**, this office

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detersive qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. **PHOSPHATE SOAP** is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of **PHOSPHATE SOAP**, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use **PHOSPHATE SOAP.**

For chapped hands the constant use of **PHOSPHATE SOAP** will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879,

To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your **PHOSPHATE SOAP** as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.

SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:

I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, Pruritus, the other an Eczema. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.,

126 O'Farrell St.

To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:

I have tried your **PHOSPHATE SOAP**, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. **HENRY H. LYNCH,**
515 Haight street.

The genuine merits of **PHOSPHATE SOAP** and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotypes plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

By S. B. CHRIST.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

CONTINUED FROM PAGE 373.

ARIZONA.—The Longvina is being drifted upon from the bottom of a 100-ft shaft, in a fine ore body which yields from \$200 to \$400 in silver. The Russian mine, Sonora, is delivering ore to the Arivaca mill, 15 tons per trip; ore carrying both gold and silver. The liberty mine has steam hoisting works completed and is raising with the same. At 70 ft depth they have three ft of high-grade mineral. The steam hoisting works of the Con. Arizona are up and at work. This mine has developed one of the finest ore bodies in the district. Mr. Fairbrother, of Stockton, Cal., is pushing work on the Reading mine near Cerro Colorado. He has a good mineral showing. A new strike has been made near the Captain Jenkins mine, which runs high in silver.

CAVE CREEK.—It is said by Tucson parties that a rich and extensive discovery of mineral has been made in Cave Creek canyon, in the south end of the Huachuca mountains. The locality takes its name from subterranean cavities which have heretofore been supposed to be natural caves, but recent exploration show that they are chambers in vast deposits of silver-bearing ore, from which at some time immense amounts of the precious metal must have been taken. These ancient workings, probably the early padres, reduced the ores at furnaces about 16 miles south of the mines, and between which points plainly-marked trails still exist. The magnitude of these furnaces is plainly indicated by the extensive ruins. The mines were recently re-discovered by a party of prospectors, among them C. F. McKinley and W. W. McAlley, who recently secured five claims, lying parallel, including two of the caves, and upon almost any portion of which rich mineral can be uncovered. A gentleman who visited these claims informs the *Weekly Nugget*, the best way to express it is, "One hundred and sixty acres of solid mineral." A correspondent writing to the same paper says that the mountain on which are the most valuable mines as yet discovered is of lime, iron, and silver, and under these crops are at not more than six inches, is the mineral. For a distance of 3,000 ft up the mountain, and 4,000 on the side there is no change in the formation, and in each place where a prospect hole has been sunk, the mineral shows, consisting of galena, sulphates, chlorides, a slight trace of sulphur and horn silver. There are 10 claims located on the mountain and each mine is a bonanza in itself. Assays run from \$90 to \$400 as far as has been tested. The nearest way to get to this canyon from Tombstone, is up Ramsey's canyon, down the head of Bear gulch and from there over the dividing range into the west fork of Cave Creek canyon, or up Ash creek, which leads directly to the east fork of the canyon. The nearest way for wagons is around the south end of the mountains a short distance into Mexico, where you strike a wagon road passing within three miles of it.

COLORADO.

SILVER CLIFF.—Prospector, Dec. 2: The Garnet, Bufalo and Ruby lodes situated in the chloride belt show mineral in generous supply running from 22 to 35 ounces in silver.

THE DIAMOND.—This is a new mine which is being developed by Messrs. French & Gilliam. At a depth of two ft below the surface they find a rock containing horn silver.

THE LITTLE ED.—Mr. Cox, who has just returned from a visit to some of the mines around Rosita, says that the Little Ed is among the mines in that section which are now giving promise. This mine adjoins the Silver Horn, which has recently developed so richly, and of which we have had occasion to speak. A shaft is now being sunk, and at a depth of 15 ft fissure vein is found revealing chlorides in trachyte, porphyry in a calcined and decomposed state, the oxide of iron and psilomelane, the binoxide of manganese. It is thought at the proper depth the same body of ore will be met as in the Silver Horn.

SILVER HORN.—Report from the Silver Horn mine comes in again to the effect that a surface crosscut of 30 ft from five to six feet deep has been driven, new veins dipping towards the main vein, bearing good ore and bidding fair to be as good as the first rich vein. Six assays made Saturday displayed the following results. They were of ore taken from the different new veins: 1,430, 1,012, 104, 106, 71, 27, average, 453.

DELMONT.—In the Delmont lode, contiguous to the Ben Franklin, the owners, Messrs. Coombs, Alden & Co., have found rich mineral in the shaft. The shaft is now being sunk along the vein. The walls of the vein strike ore of white porphyry, with a uniform width of six ft, showing a continuous lead.

VANDERBILT.—The richest body of horn silver yet discovered in the camp was brought to light yesterday. This new strike was made in the Vanderbilt, situated in the horn silver belt north of town and alongside of the Buckeye. The deposit of horn silver is one-quarter to one-half an inch thick and can be removed from the rock on which it lies, with the pick.

IDAHO.

YANKEE FORK.—*Herald*, Nov. 29: We learn from Mr. Fred Phillips that rich quartz mines have been struck on Deep creek, a country very little prospected, and lying about 25 miles westerly from Salmon City. The Yuba tunnel has tapped the Atlanta lode at a depth of 1,500 ft and struck a body of rich ore. The tunnel is 1,400 ft long and situated near Atlanta. The furnaces are in operation again at South Mountain, and the Mono and other mines are yielding good rock.

MONTANA.

BOULDER DISTRICT.—Butte *Miner*, Dec. 2: Mr. R. G. Abernethy, of this city, returned last evening from a visit to the Boulder district, bringing with him several very fine specimens of silver quartz, obtained from a prospect opened by the Silver Glance mining company, composed of Messrs. Abernethy, Smith & Hull. Mr. Abernethy speaks in very flattering terms of the future prospects of the Boulder district as a mining camp, and reports that a number of equally promising veins have lately been discovered, and that men of capital have lately paid visits to the district with a view to making investments in some leading property. The specimens which are the property of the owner of the Silver Glance showed us, assay as high as \$200 to the ton in silver.

GLENDALE.—Recent reports from Glendale are of a very encouraging and satisfactory nature. We have received positive assurance from the highest authority that there are no doubts as to the consummation of the Hecla sale. The terms of the transfer are the payment of \$1,000,000, the parties disposing of the property to take some stock of the new company. The ore and bullion on the dumps and at the smelter, to the value of \$500,000, are to be retained by the present owners of the property.

THE STEPHENS LODE.—This very promising property is owned by Mr. John Stinson, who has leased the mine to S. J. Stewart, under whose energetic management work is now being prosecuted. From the bottom of a 50-ft shaft a level 50 ft long has been run to the west, striking a three-ft vein of free-milling ore, the assay value of which is in the neighborhood of \$60 per ton in silver. The daily product is about four tons, which is shipped for reduction to the Dexter mill. Fifty tons of good ore are now on the dump.

OREGON.

ITEM.—Jacksonville *Sentinel*, Dec. 2: Messrs. Watts & Redman, on Horse creek, in Josephine county, discovered what they believe to be a rich quartz ledge. The specimens of quartz found are highly impregnated with the precious ore. Having made the necessary arrangements they will at once wash off the top dirt in order to lay bare the ledge. The indications are all favorable for a rich strike.

UTAH.

ROMULUS STRIKE.—The Silver Reef *Miner*, published in Washington county, Utah, says: The recent strike made by Edward Loughney and partners in the Romulus mine, on Grapevine Wash, has been the subject of much comment during the past week. Everybody agrees, however, that the strike is a good thing for the camp as well as for the lucky owners of the claim. Mr. Loughney informs us

that the ore vein shows up bigger and richer with every stroke of the pick, and he is confident that he has got a bonanza within the boundary lines of his claim. The last two assays made of average rock showed \$32.96 and \$121.27 per ton. Since the above was put in type, three more assays have been made from unpicked samples, showing \$294.13, \$143 and \$52 to the ton.

WASHINGTON.

QUARTZ LEDGE.—The *Astorian* says: A very valuable quartz ledge, containing gold, silver and lead, has been discovered recently near Columbia Center, Columbia county, Washington Territory, by John Decras.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

APPARATUS FOR GUIDING HEADERS.—Joshua Steves, Stockton, Cal. Patented Dec. 24, 1879. No. 220,210. In ordinary headers, at the rear end of the beam or pole, is placed a vertical post, to which is attached, by means of pins or staples, the upright, on the lower end of which is the caster wheel, supporting the rear end of said pole. At the upper end of this upright is a horizontal tiller or guiding bar, for turning the wheel so as to direct the machine in a straight line or turn it around. The driver usually stands on a board on this pole, so that the tiller comes between his legs, and then he can operate the tiller by the movements of his body, and use his hands in moving the levers controlling the cutters. It happens frequently that in turning sharp corners or curves the driver will have to push this tiller way off to one side, and at the same time have to stop to operate the lever, both operations being difficult to do at once. The tiller is then so far off to one side, and has to be held there, that the man must lean over to that side to manage it, and at the same time operate the lever. Moreover, with the tiller made and worked in this way, the driver cannot sit, but must at all times stand up. The inventor has devised a means of guiding the header by which the driver may sit and operate the lever and tiller at once without any inconvenience. This invention will be found a great improvement in guiding headers, since it overcomes one of the most serious difficulties in this class of agricultural implements.

CAM FOR STAMP MILLS.—Lewis A. Moore and John Dykes, Orena, Humboldt Co., Nevada. Patented Nov. 18th, 1879. No. 221,738. This invention relates to certain improvements in the construction of cams, which are commonly used in lifting the stems and stamps of quartz mills by means of the tappets; and consists in forming a removable shoe or faces attached to the body of the cam by means of bolts, and placing between said body and shoe a cushion or packing of any elastic substance that will yield or spring under the blow of the cam on the tappets, so as to reduce the jar attendant on the sudden contact.

NEW AUSTRALIAN RAILWAY.—A railway recently undertaken over the Mount Lofty range of hills, South Australia, will in years to come be regarded as one of the greatest engineering works at the Antipodes. However insignificant gradients of 1 in 45, and ascents of 2,000 feet may now be, anyone who travels on the future line, or inspects the earthworks and tunnels as they are now being made, cannot fail to regard the line as a bold step for a small community to take. Nearly £750,000 will be spent on the 33 miles between Adelaide and Nairne. Within a trifle the railway is estimated to cost £22,000 per mile, and that, too, through a country where the cost of the land is a mere bagatelle. In some parts the expenditure will be fully £30,000 per mile, owing to the large amount of tunneling to be done, and the height of the viaducts and embankments to be formed. The summit of the range will be reached in 18½ miles from Adelaide, at a point about a mile to the west of Chafers, and at an altitude of 1,630 feet above sea level. Here a station, to be named after the range, the Mount Lofty station, will be built. The ruling gradient, 1 in 45, will be between Government Farm and this point, and the descent from the summit to the Aldgate pump will be by a similar gradient. Powerful engines will have to be used, and they will come down to Mitcham without the aid of steam. The mountain section begins about Mitcham, and with but small exceptions the gradient is 1 in 50 until the Government Farm is approached. But in order to secure even this gradient, creeks have to be crossed, steep hillsides dugged, mountains tunneled, sharp curves made, and ravines spanned by viaducts of great height.—*Scientific American*.

INTERMITTENT PHYLLOXERA.—It seems that the vine pest in Australia is manifesting some of the hesitating behavior which characterizes it in this State, and not proceeding forthwith to "occupy the land" as in France. The government inspectors of Victoria report that the insect has not been detected outside of the Geelong district, also that the ravages of the insect have been much less virulent this season than last, which fact strengthens the hope that the disease may be yet successfully stamped out.

Classification of Metalliferous Veins.

A very interesting paper from Melville Attwood, Esq., was read before the San Francisco Microscopical Society on December 4th. The subject of the paper was "The Importance of a Classification of Metalliferous Veins." In substance Mr. Attwood says: Of all the speculative employments, mining is, perhaps, the most uncertain. Miners of great experience and ingenuity are frequently at fault, and sometimes completely defeated in their search after paying ore-bodies and the mines abandoned, while men of less ability have afterward worked the same mines, from which they have derived large profits—so that any plan or method that tends to throw light on the subject, and assist the miner in his explorations, should be considered of value.

The proper classification of metalliferous veins or lodes (I prefer this Anglo-Saxon word, lode), appears to me to be one of the first things required, and it seems surprising that, where such vast interests are at stake, it should have been so totally neglected.

As far as I am able to judge, the only way in which lodes can be correctly classified is by their enclosing rocks or the rock formation in which they occur, thus rendering an accurate determination of the enclosing rocks necessary. Some rocks are of a coarse and simple structure, and their mineral constituents may be resolved by the unaided eye, but by far the greater number are of so fine-grained texture as to defy ocular analysis, so that for their determination the use of the microscope is indispensable. For instance, totally different rocks sometimes have the same chemical composition and are similar in external appearance, but a microscopic examination shows the internal structure to differ greatly. A classification of lodes would do much to stop the misuse and confusion of common mining terms, and many hackneyed phrases, such as "regular and well defined walls," "clay walls," "true fissure veins," "perfect formation," etc., would be abandoned. Some of the most productive tin lodes in England have no walls, and the vein-stone appears to be an altered granite. Again, the richest mine in Nevada—the Comstock lode—has only one, the footwall, the rock a dolerite. The principal gold lodes of California—the Eureka and Idaho, of Grass Valley, the Amador, of Sutter Creek, and others—can only be said to have a "hanging wall," the rock of which is generally a diorite or diorite, the latter being considered the ancient form of dolerite; so that "regular and well-defined walls" are not so good an indication of mineral wealth as is generally supposed.

Last year I had the pleasure of calling your attention to a simple mode of preparing rocks for examination of the outer surfaces with the assistance of a common pocket magnifier, and which I then thought would be of great assistance to the miner, in helping him to correctly determine the character of many of the enclosing rocks, and in many instances it was quite sufficient; but for a correct determination, after all, the microscope must be used, and at that time a cheap and easy way to cut the rock-sections was the difficulty I had to contend with. After many experiments, I found a simple plan by which it can be done at little cost and labor, by the use of a few emery stones, or blocks of different degrees of fineness—say, from one and a half to two inches square, and eight or nine inches long—the same as I have brought here for your inspection. The chips to be cut should be first made as thin as possible; the plan recommended by Mr. Rutley, to use a cold-chisel, the end let into a block of wood, and then by holding the specimen on the edge of the chisel, and striking it a sharp blow with a light hammer, will generally give you a satisfactory chip. The chip must then be rubbed on the emery blocks, with water, till you get a good, even surface on one side of it, commencing with the coarse emery blocks first; then, with Canada balsam, fasten the smooth surface of the chip to a common glass slide, which is done by heating the slide over a spirit lamp, and then applying a small quantity of the balsam. As soon as the balsam liquefies, press the smooth surface of the chip into it, and then allow it to cool. The balsam is better to be dried, so that you can use it like a stick of sealing wax. As soon as the slide and chip are cold, you can commence to rub the outer or rough surface of the chip attached to the slide, on the emery blocks until you get it nearly thin enough for mounting. To finish, use the fine, smaller blocks as you would a file. You can hold the section up to the light and examine it during the operation. Mount and cover the section with thin glass, in the usual way.

Amongst the specimens in the case which I have brought for your examination are two marked Nos. 1 and 2, which were cut in London, England, by a professional, with expensive apparatus. Those marked Nos. 3 and 4 are from the same rock but cut by myself, with the emery blocks, in the way I have endeavored to describe to you, and, if the mounting material was of as good quality, would be equal to the former in every respect.

In conclusion, it will give me great pleasure to show any of the members of this society how to cut and mount the rock sections at any other time. At some future meeting I hope to be able to give the society the result of my examination of the clays of the Comstock lode, the

most interesting and important work I have ever yet undertaken.

A vote of thanks was tendered to Mr. Attwood for his very interesting paper, and the society adjourned.

News in Brief.

In Upper Silesia 150,000 persons are suffering from famine.

There has been a heavy snow storm throughout Hungary.

A BATTLE occurred recently between the Montenegrins and Albanians, in which the latter were repulsed, great loss being inflicted on both sides.

THE mass-meeting to excite public interest in the World's fair of 1883 has been postponed for a month, in the hope that Gen. Grant may then be able to attend.

In New York Government bonds are quoted at 103½ for 4s of 1907; 102½ for 5s of 1881; 105½ for 4½s; sterling, \$4.83 @ 4.85; silver bars, 114½; silver coin, ½ @ 1 discount.

THE MULTIPLEX COPYING TABLET.—This is one of the latest improvements for lessening clerical labor. By writing on any kind of paper with a peculiar copying ink and laying the written page on the prepared tablet a reversed impression is given from which fifty or a hundred copies of the original may be made. Circulars, letters, etc., may thus be duplicated rapidly and with better labor. There are several forms of this character of tablet in the market, the difficulty with most of them being that the ink is hard to remove from the tablet. In the Multiplex, however, this difficulty has been overcome, the ink being readily wiped off. The composition is put up in a neat wooden box properly lined and ready for use at any time.

be supplied through this office at published rates.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from scouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

PATENT LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

THE FAR-FAMED

AMERICAN LUBRICATOR.

Patented November 14th, 1876.

The American feeds oil into the steam pipe of the Engine, at a point above the throttle valve, thus infusing the STEAM WITH FOAM OF OIL, and as the Lubricated Steam passes through the Throttle Governor, Steam Chest and Cylinder, it Lubricates all those parts.

EVERY DROP OF OIL IS VISIBLE as it passes into the steam pipe.

It imparts a regular motion to Engines, because it Lubricates the Governor Valve.

It will pay for itself in fuel every two months, in Oil every seven to 10 months, in wear, packing and labor every four months.

It does all the above with absolute constancy, and with the small amount of Oil as shown in Catalogue, which please send for.

For Sale by

The Multiplex Copying Tablet.

This is Something New and Valuable.

By simply writing with copying ink any number of good plain copies up to 100 can be produced with great speed. It is a great and remarkable improvement. It is manufactured by WILLIAMS & BOURNE, 612 Clay St., S. F.

Letters which Speak for Themselves:

SECRETARY'S OFFICE, WELLS, FARGO & CO.: Gentlemen:—I have tried your Multiplex Copying Tablet, and can cheerfully say that I have found it very much superior to three or four of the same processes which I have experimented with, and it is the best I have seen.

Yours truly, CHARLES W. BANKS.

San Francisco, Nov. 17th, 1879.

OFFICE CHIEF OF POLICE:—Gentlemen:—In reply to your request to give my opinion of your Multiplex Copying Tablet, which has been in use in this office for some time, I would say that it works easily and rapidly, performs good service and gives perfect satisfaction, being superior to anything of the kind used heretofore.

Yours Respectfully, JOHN KIRKPATRICK, Chief of Police.

San Francisco, Nov. 13th, 1879.

The MULTIPLEX is superior to all others for the following reasons:

First—It will produce a very sharp and clean copy, and over one hundred impressions may be taken with excellent result.

Second—After copying, THE INK MAY BE WASHED FROM THE TABLE ALMOST INSTANTLY.

Third—The composition is put up in a neat wooden box, properly lined, and is not so readily affected by climatic influences.

PRICE LIST:

Postal Size, 4x6..... \$1 50 | Large Letter, 9x11... \$5 00

Blake's Sectional Cushioned Crushers.

The accompanying engravings illustrate a very important improvement recently made in the well-known Blake ore crusher. In the new machine, the "Challenge Rock Breaker," the heavy cast-iron frame of the old form of crusher is dispensed with, and the main tensile strains, due to the crushing between the powerful jaws, are brought upon wrought iron or steel instead of cast iron. This improved construction makes the machine much less bulky and lighter, as well as very much stronger.

The construction of this machine is shown in the engravings and its operation will be readily understood. A three-sided frame-work of cast iron, with broad flanged base, holding the movable jaw in suspension, forms the front part of the machine, between the upright convergent jaws of which the stone is crushed.

The jaw shaft is held in place by wrought iron or steel clamps, C, which serve to take part of the strain due to crushing in the upper part of this jaw space, and also serve as walls thereof. In the lower part of this three-sided frame or front part of the crusher, and on each side of it, are holes in the casting to receive the main tension rods which connect the front and rear parts of the machine. The rear part, B, is called the main toggle block, and is also provided with holes for the tension rods, R, R, corresponding to those in this front casting.

These two parts of the machine are connected by the main steel tension rods, R, R, each provided with screw thread and nuts, by which their lengths and the jaw opening are readily adjusted to crush coarse or fine, as may be desired.

The front and rear castings are supported on parallel timbers, to the underside of which are bolted the boxes carrying the main eccentric shaft, provided with fly wheels and pulley. The timbers are thus made component parts of the machine, and take the transverse strain which comes upon the pitman connecting the main shaft, and the toggle joint placed in the rear of this movable jaw, and between it and the main toggle block.

Between the broad flanged bases of the front and rear castings and the timbers on which they rest, are placed flat rubber cushions one-quarter to three-eighths of an inch thick. Every revolution of the shaft brings the toggles more nearly into line, and throws the swing jaw forward; it is withdrawn by the rod provided with rubber spring, L. In this way a short reciprocating or vibratory movement is communicated to the movable jaw.

This new construction of the Blake stone crusher—while the principles of crushing between upright convergent jaws is the same as in their old machine, evidently possesses many and great advantages over the old forms. It is sectional. The weight of the heaviest piece in crusher size 15x9 inches is about 2,400 pounds instead of nearly 8,000. The rigidity inseparable from machines with cast-iron frames, and which is the cause of frequent breakages, is completely overcome, and the longitudinal as well as transverse strains are brought upon materials which are strong and elastic as compared with cast iron. The rubber cushions, while offering sufficiently great resistance to compression in case of the breakage of stone or in doing the normal work of the machine, will, in case of the accidental intrusion of steel hammers or anything of that kind, be compressed and so permit the partial revolution of the fly-wheels before coming to a full stop, thus relieving the machine of those nearly infinite strains to which those of the old form were subjected, and which resulted in the breakage of important parts. The toggles are long, and of equal length and may be worn indefinitely as compared with those in the old machine.

The construction of the pitman is such as to admit of change of inclination of the toggles, and consequently of adjustment of the length of stroke of the movable jaw. The jaw opening can be varied between any working limits by means of the nuts on the tension rods, and the machine be set to crush coarse or fine as may be desired. The crusher, it is stated, can be run at a higher rate of speed with safety than

either of the old forms of crusher with cast-iron frames, and will consequently do a greater amount of work. The manufacturers inform us that while this machine is very much lighter than the old forms, it has at least double their strength.

This new rock breaker has been repeatedly subjected to the test of a steel hammer being thrown between its jaws, when going at as high a rate of speed as 300 revolutions per minute, without injury to or breakage of the machine.

The improved machine is the invention of Mr. Theodor A. Blake, mining engineer and Secretary of the Blake Crusher Company, of

A Good Mining Season.

The outlook for this hydraulic miners the coming season is exceedingly gratifying. A great deal of water has fallen, soaking the ground pretty deep and the snow will hold well. The season has begun with very good prospects. From all directions we hear of the mines having plenty of water, and as most of them were prepared for the rush of water, they are able to utilize every inch that comes to them. The early rains have furnished water for mining in

Fig. 1

THE BLAKE CHALLENGE ROCK CRUSHER.

New Haven, Conn. This gentleman is well known on this coast, where he resided for some years, in the pursuit of his profession. He was at one time Corresponding Secretary of the California Academy of Sciences. One of the improved machines may be seen at the Union Iron Works, on First street, Messrs. Prescott, Scott & Co. acting as agents for this coast. Several sizes are made, from 10x7 up to 15x9, the dimensions indicating the receiving capacity of the machines in inches.

A DISASTROUS BLAST.—We see by the Nevada Transcript that a big blast put off this week at

dry gulches and the ground has been made softer for prospectors. The mining community hopes for a very wet season, so they will get an abundance of water for their work. The currents of the mountain streams are all rapid and full and the harvest of the miner is now being reaped.

The quartz mining prospects are also of a hopeful character. More attention is being turned to California properties than has been the case for many years. It is found that they pay better in the end than more brilliant looking schemes afar off. The era of railroads, good wagon roads, cheap supplies, etc., has had an

Fig. 2.

LONGITUDINAL SECTION OF BLAKE CRUSHER.

the Polar Star mine, Dutch Flat, did some very serious damage. A number of people had gathered to witness the explosion, and as it only forced out the face of the bank, large boulders were thrown among the crowd of people, mashing one man's foot, breaking another's arm, and seriously wounding a number of others. The blacksmith shop was demolished, and a lot of hydraulic pipe ruined.

FOURTEEN THOUSAND immigrants arrived at New York during November. Since January 1st they number 125,000, being an increase of 49,755 over the corresponding period of last year.

exceedingly beneficial effect on the California mining interests, making profits greater and leading to many new developments. Hundreds of old mines are being re-opened which ten years ago were valueless. If we could only find a cheap method of working our sulphureted ores the quartz mines of this State would be more than doubled in value.

COPPER MARKET.—Our latest advices from the East show a firmness in copper, with moderate sales. Holders refuse to sell for spring delivery except at an advance of 10%. Prices remain unchanged, as will be seen by our market reports.

The Want of Custom Mills.

The great want of most of the mining communities on this coast is custom mills, where working miners can have their ore treated fairly and honestly for a suitable compensation. The establishment of a big private mill for some wealthy mining company in a new camp is by no means all that is necessary to bring that camp out of obscurity into prosperity. If successful, it will bring notoriety to the camp and to the company, and even if not successful, it will enable the owners of the stock to give it a marketable value upon which to speculate, which would seem the only reason, in many instances, why mills were built.

It is not works of this character, however, which build up a camp, nor have the operations of the largest mines so exclusive an influence in this direction as is commonly granted to them. True, a big mine may employ a number of miners and draw the attention of capitalists toward the corner of the country where it is located, but even this is not always to the benefit of the camp itself. If the capitalist owns the mine, just so much or so little money, as is necessary to run it, is spent there, and the rest of the bullion goes to the city to be invested elsewhere, or to swell hoards already large. It would be better for the country to see the money scattered among the many than he accumulated by the few. We do not speak in any socialistic spirit, but would like to see the mining districts themselves prosperous, as well as the city, to which most of the money from the mines finds its way.

Without custom mills the prospector, discoverer and miner must sell his mine before it can be developed. What remains for him then is to repeat the operation—a thing not always easy to do—or to go to work by the day on the mine which was his own. As a general thing, the miner himself gets no very fancy price for his ground—the middle men, "holders," "placers" and incorporators are the lucky ones in such transactions.

How much better would it be for miners to own their own small mines all over the country, as the farmers own their farms, and work them for their own good and profit. The farmers can't afford to own threshing machines and engines, many of them, yet these machines travel about from farm to farm, and put the farmer's crop in marketable shape for him, without stealing very much of it, either. The miner half the time can't even find a place to take his produce to, much less get it put in shape for market.

There are lots of places all over the coast where, if a mill were put up, the opening of scores of mines would be insured. The wonder is, that some big company has not been organized with this object in view, long before this; to find out by proper investigation suitable locations and start small custom mills, on a fair and honest basis—no charging a high price for crushing and then stealing half the amalgam. Then by and by either sell or remove the mill, or keep it running as the prospects indicate.

With custom mills, the miners themselves would reap more of the results of prosperity of the mines. They would not be so dependent on the capitalists. They would not see all the bullion produced going out of their reach a few hours after it was produced; and they would be encouraged to prospect and open new mines. What encouragement is there in working six months to open a mine and take out ore with no chance to make a cent except by sitting down to wait for some one to buy the mine, not the ore? What encouragement is there even to prospect very much, in a region where there is no custom mill, or where there is one under dishonest management? It is to the custom mill that all distant camps are to look for their prosperity, and we would rather hear of one going to a camp than to hear of half a dozen for private companies. The private ones don't help prospectors much. All new districts need them. The southern and eastern part of our own State, Arizona, New Mexico, Idaho, Montana, Nevada, in fact all the mining States and Territories, want ten custom mills where there is now one.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Quartz Mining in Amador.

EDITORS PRESS:—This county is justly celebrated for its gold-bearing quartz. In this respect it has always ranked among the foremost in this State; nor is it likely to lose its prestige soon if the present and its prospects are any index of the future. With rare exceptions, such as the Downs and others at Volcano, the principal and most profitable mines are found on the mother lode, or central belt, extending the entire length of the county from north to south. Much prospecting has been going on lately all along this line, as well as in other parts, resulting in some important developments.

A large area still remains to be explored. In some counties, richer specimens of ore may have been met with, but few, if any, can offer a safer field for investment. The gold, in places, is so evenly distributed through the quartz that the whole is worked with a profit even where of low grade—the run being made with a full quota of stamps and a due regard to economy in other respects. A brief allusion to points visited and mines adjacent is now in order.

Ione City,

The terminus of a branch road connecting with the Central Pacific at Galt, Sacramento county, is more like a village than a city, taking its appropriately charming name from the no less heartful valley in which it is situated. There is a copper mine in the vicinity, and several coal mines in active operation.

Jackson, the County Town,

Is somewhat more pretentious, having some 1,500 inhabitants, all told. Less favored than Ione, in good farming land, in mineral resources, it possesses many important advantages, located as it is, near some of the most productive mines of both Amador and Calaveras counties. The present outlook, in its more immediate vicinity, is also said to be unusually good, having had some fresh blood infused in the form of San Francisco capital.

The Zeile, an old mine under a new name (and, to be hoped, under better auspices), has had the shaft retimbered and hoisting works erected with a capacity sufficient for a depth of 3,000 feet; while all is life and bustle to get the new 40-stamp mill in readiness by February next, the same to be equipped with 16 Frue concentrators and all other first-class appointments.

The Moore is looked upon as a good mine, but at this time is greatly in need of a similar helping hand as that recently tendered to the Zeile. It has reached a depth of 250 feet. Lode from 3 to 10 feet thick, with a large body of low-grade ore. The entire property consists of 120 acres, on which there are several other promising veins.

The Monterichard, at the depth of 425 feet, shows a three-foot vein of ore which averages about \$8 per ton. The 10-stamp mill is kept steadily running. The mine is said to be paying well and to have paid from the start.

The Oneida, midway between Jackson and Sutter Creek,

Belongs, perhaps, as much to one place as the other. It has been worked, with varied success, for 25 years, and for the past 14 years almost uninterruptedly. Linear extent, 6,000 feet; width of vein, 6 feet; greatest depth, 1,350 feet; size of mill, 60 stamps; number of men employed, upward of 100. From tests made from ore taken from the lowest level which is now being opened, the company are led to hope that it will prove remunerative.

The Lincoln still continues to pay well, the 40-stamp mill at present running on rather low grade ore.

The Con. Amador have abandoned the old mine (where one of your capitalists struggled long and manfully with ragged poverty at his door), and are now down 450 feet on the north. At this point there is a large extent of virgin ground, which had been previously prospected by shaft with such favorable promise as almost to make success a certainty.

The Amador Canal & M. Co., with office here, furnishes the motive power for nearly all the mills of the county—main canal, 45 miles; inclusive of distributing ditches, upwards of 100; receiving water from main fork of the Mokelumne river and large reservoirs in the mountains, embracing the Blue lake of Alpine county.

Amador County

Is a very flourishing place, built up chiefly by the Bunker, Original Amador and the Keystone, giving employment to hundreds of men, with mills and works on a grand scale, and disbursing immense sums annually. The Bunker is a 3-foot vein, depth, 450 feet, the rock working from \$3 to \$11 per ton. It is somewhat a matter of regret that facts and figures for publication could not be obtained in regard to the last two, particularly as to the Keystone, its reputation at home placing it among the best paying mines of the State. The South Spring, adjoining, and the Talisman, still further south on the same range, are said to continue their promise as developments progress.

Following the main belt in a northerly direc-

tion from two to three miles, there are found a large number of locations in

The Vicinity of New Chicago.

They have all been opened to a greater or less extent, and generally look very encouraging. The greatest depth (1,000 feet) is in the Gover, which has had a large body of water to contend with. This is now under control. In the 700 level north, as also in the 900 level, a body of fine ore, six feet thick, is reported. Among the other claims here may be mentioned the Maryland, Seaton, the California, the Hazard, the Nevada, and the California North—the last named at 200 feet depth, showing a 3-foot vein, with ore from \$3 to \$15 per ton. The Nevada and some others prospect so well that the owners think they have a second Keystones.

Plymouth and its Mines.

The principal mine, and laying claim here to be among the best in the State, is the Empire, paying from \$30,000 to \$50,000 per month. The citizens may be pardoned for glorying a little in its richness, as under its potent spell the place has evidently had a very rapid growth, and is still spreading as a "young hay tree" of Palestine, the large number of new buildings giving it a very fresh and lively aspect, contrasted with the old and dilapidated look of many mining towns.

Some Facts as to Mine and Mill.

Greatest depth of mine, 1,200 feet; width of ore, 50 feet; length of present pay chute, 600 feet; number of stamps in mill, 80. Mine said to have ore enough in sight above the 1200 level to keep mill running 10 years. Steel cams and tappets, after thorough trial, preferred to those of cast iron. A 20-inch wheel of the Company's devising, cast at the foundry of Donnelly & Co., Sutter Creek, gives better satisfaction than any other of the kind used. Their belts from a New York house are thought to be unrivaled in their line. They are composed of two broad bands of leather, with a like width of thick canvas cloth between; the whole firmly riveted together.

An Ingenious Contrivance.

In connection with the mine are six engines, all exhausting their steam into one common boiler, from which hot water is taken for all the others. To this boiler is attached a syphon through which a supply of cold water rises a sufficient height to give a fall of 40 feet, condensing all the steam from the engines, and at the same time causing a vacuum which is thought to give a pull equal to 25 pounds of steam, thereby making a saving as they claim of at least three cords of wood in 24 hours.

Of the other claims here, the Reese, owned by Messrs. Hayward & Woolford, has a 60-foot shaft and a five-foot vein, the ore being put at about \$10 per ton. The Pacific, immediately south of the Empire, is eight feet in width, and the Fort Johns, still further south, is represented as having a very large body of ore, mostly low grade.

All the places from Jackson on the south to Plymouth on the north are situated in the order named, and follow what is known as the main belt. It remains now to be seen from a few cases of

Quartz Operations Around Volcano

That all the good mines are by no means confined to this belt. The Downs, for a small mine—vein from three to five feet—is looked upon as one of the most profitable in the State. Its average yield is \$40 to the ton of ore. The rock of the Stewart and Gillick is put as high as \$30 per ton. The Griesbach is well spoken of, value of ore not learned. Robinson & Jones claim \$10 (working process) from a four-foot vein, and also from a smaller vein two to three feet wide, from 300 to 400 tons in sight that will run as high as \$25. Mr. W. P. Sargent, Superintendent of the Golden Gate Consolidated—property of a Boston company—has sunk 100 feet since taking charge, making now a total of 300 feet and has run levels of 40 feet north and south on a three-foot vein of fine ore. He places it from \$30 to \$40 per ton. Making all due allowance for over estimates in some instances, few towns can make any better showing. Then there is the Tellurium at Pine Grove in this same vicinity, that claims \$565 from a crushing some time since, of 18 tons of ore; and now the company report a strike of some very rich rock which they rate somewhere from \$50 to \$75 per ton. Their mill will soon be run by water, vice steam as heretofore, at a very considerable reduction in the way of expense.

Hoping that they and all others here may be happy in the realization of their brightest anticipations, I remain as ever yours,

A. C. K.

Marin County Gold Mines.

EDITORS PRESS:—The above heading may be considered by some to be only figurative language alluding to the rich, golden hutter—their pride and livelihood; no, sir, not figurative, but a plain fact, that Marin county, too, has gold-bearing quartz.

It is said that when the North Pacific railroad was graded, some gold was discovered near Nicasio station, in White valley, about eight miles from San Rafael; but this resulted in no permanent locations. In 1877, Mr. Peck, of San Francisco, and three others, visited the valley, bringing with them what they called a "magnetic divining rod," and proceeded to search for mines. They soon found favorable noddings of "the little joker," as it is more commonly called, and proceeded to make title

to their find by locating four claims of 750 feet each. Being a Spanish grant land they were obliged to respect the rights of Mr. R. K. Rogers, the owner of this ranch. From him they obtained very favorable terms and ample privileges.

Their recorded contract with Mr. Rogers, allows them four years working privilege, and of all the gross proceeds of the mines they give Mr. Rogers one-twentieth as rental or recognition of his right in the realty. The miners have the right to purchase the mine at any time for \$30,000.

About one year since they had such favorable prospects as seemed to warrant the expense of steam hoisting works, which they now have erected under the superintendency of Mr. A. C. Burrington, who has shown ability and economy in all his plans and outlays. Have shaft down 200 feet and tunnel drift from bottom of shaft 215 feet, all the way in ledge matter with frequent streaks of good quartz, and some assaying as high as \$90 per ton. They propose drifting on till reaching the north hanging wall of the ledge. Have had hard blasting rock all the way, but the strong Giant powder and drills do successful work. A small blower with tin tubing gives them plenty of fresh air. The prospect at this early stage of development looks certainly quite encouraging. Some choice specimens show rich in gold to the naked eye. The ledge holds outcrop, and a lad broke a nice specimen of quartz gold from the outcropping rock.

The location for mine and mill is admirable; wood very abundant, and redwood timber on the hills near by, in the midst of excellent ranches, Nicasio railroad depot close by, and also near to the powder mills.

I was told at the mine that Governor-elect Perkins came, saw, and purchased an interest in the mine, not from any faith in the "little joker," but from the showing made by powder and pick.

Whoever views the San Geronimo mine will congratulate the locators, and commend their good judgment in a wise selection of a place to use their little joker. And even those who may believe the joker (under any of the names it has borne for the past 100 years) to be a fraud, will not withhold their best wishes for full success in this enterprise.

The mine employs 13 men in all, paying tub tenders \$2.50, miners \$3, and engineer \$3.50.

Some prospecting is going on in different parts of the county for gold. Mr. Murray, near Nicasio, is in danger of finding coal oil. He has found some of the Santa Cruz gas in his tunnel, which, on being ignited, singed his whiskers. It is for further development to say what his find is worth. If further off it might be a big thing, but it is too near market to be valuable for speculative purposes.

December 1st, 1879.

B. W. C.

Oil Wells and Refineries of Southern California.

The Mercury of San Buenaventura in a late issue thus mentions, through a correspondent, the growing oil industry of our southern counties: There are some five oil wells at San Fernando; depth from 200 to 600 feet. The refinery, at which these oils are prepared for use, is at Pico, near Newhall. It is at these works at Pico that the oil from Moody's gulch is refined. These five wells and refinery are in Los Angeles county near the southern border of Ventura. There are in Ventura county, on what is known as the Exmission lands, eight wells from 100 to 200 feet in depth, all of which yield oil by pumping; some more and some less. But two of them at present are in operation, owing to the low price of oil in market. The two that are in operation yield 30 barrels a day. There are also six tunnels that yield on an average three barrels a day.

There is a well at Sespe 1,500 feet deep that yields 100 barrels a day. This well is owned by a Los Angeles company, but most of the oil is brought to San Buenaventura for refining. They have in contemplation piping it to the refining works in this city. The distance is 25 miles, and the estimated expense is \$2,500. There are three refineries in this city with a refining capacity of 150 barrels a day; one of them at present is devoted to making tar. The second one, owned by E. A. Edwards, is running on kerosene and lubricating oil. The kerosene, or burning fluid, is the clearest I ever saw. The lubricating oil is equally fine and is used on sewing machines and other fine machinery. The works at present are turning out five barrels of lubricating oil daily, and from 10 to 20 of kerosene. The capacity is 25 barrels. The third refinery had been running on kerosene but a few weeks and was blown up last Friday. The works somehow got on fire, and the hands in and about the building, perceiving their imminent danger, hastened out and away from the building, and threw themselves flat upon the ground so that the flying missiles passed over their heads when the explosion took place. There was no bodily injury, and the works will be running again in a few weeks.

These oils are heavier and clearer than the Eastern oils; make a better light, and are sold at the works at 15 cents per gallon. All the oils in southern California contain less volatile and explosive matter than the product from any of the Eastern wells, consequently it is more easily refined and safer to use, and is taking the place of Eastern oils in all our Southern towns.

El Dorado County Mines.

A correspondent in the *El Dorado County Republican* of December 11th gives an excellent description of the mines of El Dorado county, particularly of the Pilot Hill mining district, which the writer seems to think is regarded as a lost camp, and undeservedly passed unnoticed by those in quest of mining investments. Little mining is done there now except during the winter months while free water abounds. The outlook for quartz mining is most encouraging, but the total absence of machinery to reduce ore, and the heavily tolled bridges that separate the prospectors from the more favored mining districts across the river, preclude the regular prospecting for quartz by the miner when must work for present returns during the limited period of free water.

An exception to the intermittent character of mining operations is the Boulder mine. Its name was derived from some large quartz boulders found in the claim, from which gold, well into the thousands, was extracted. The formation, cement gravel, round and water worn, from the size of small pebbles to huge boulders (like the bed of a river), has to be worked up by powder previous to hydraulic operations, and the amount of rock to be removed and piled away after every run of water adds much to the expense of working. The claim is peculiar, it varies in depth from the rim rock to 35 or 40 feet of hard cemented gravel, and as there is no other ground of a like description anywhere in the neighborhood, how it came there is a matter of conjecture. It is the opinion that this entire flat at one time formed a part of Pilot Hill, and by some convulsion of nature was dislodged and rolled down to its present position. An immense quartz ledge, corresponding to the huge quartz boulders in the mine, is to be seen on the hill, in a position to carry out this hypothesis.

The Pilot Hill mine is very favorably spoken of. Various auriferous quartz seams run through the location and several shafts have been sunk, from all of which more or less rich ore has been obtained. The main shaft, down about 40 feet, shows two good quartz seams 8 to 12 inches thick, and one smaller one. The country rock is very hard and full of mineral, and a strong body of water exists. This, however, is presumably surface, and can be overcome by drainage, which, from the position of the mine, is attainable. The ore contains a large percentage of rich sulphurets. The owners, Messrs. Mendes, Raimundo and Warner, believe that the various seams converge into a solid ledge at no great depth, and that they have a valuable mine. They can, however, do but little beyond the requisite legal amount of work per annum, to hold their claim, until they can induce capital to aid them in developing it. The ore now lying on the surface would pay \$25 or \$30 a ton had they any machinery within a reasonable distance to work it. Pilot Hill occupies a large area of mineral ground. At the western base of Pilot Hill lies Cooper's ravine, in which is located a soft chromite mine, with a well-defined ledge some 12 feet thick.

Many fine specimens of gold in quartz, found in the neighborhood of Cooper's ravine, indicate that quartz ledges worth looking for exist in the hills about; and several quartz locations that have been partially prospected, give good encouragement for more practical examination.

The Hunt mine, near Hogg's Diggings, is the only patented mine in the vicinity; it is about four miles north of Pilot Hill, and is owned chiefly by Sacramento people. In early days, up until about 1859, a small and very imperfect stamp mill, on Hogg's Diggings, operated the culled croppings from the ledge (which is well defined for over a mile), and the ore from some few shafts varying from 29 to 40 feet in depth, with an average return of \$15 per ton. The owners have done nothing to this property, save keeping trespassers off, since acquiring their title.

Unsorted samples of ore from the Josephine, on Knickerbocker creek, have assayed upward of \$25 per ton.

Only a short distance from the Josephine, a good find of very rich gold in quartz was made by Mr. Thos. Stephens and partner, about a year ago; they have since been prospecting for the ledge, and are very sanguine of making a successful mine.

Generally speaking, the miners of this section are not accustomed to quartz mining, but the introduction of mining machinery, and the opening of the mines, would at once introduce the operatives ever ready to attend the excitement of a new development.

Water power can be obtained, and wood is plentiful. The distance from Auburn is 10 miles by the road, and four across the river; from Folsom, 18 miles; from Newcastle, across Rattlesnake Bar bridge, 12 miles, and 18 miles from Placerville, renders Pilot Hill accessible from all points; a daily stage line passes through from Auburn to Placerville. Three good stores, a postoffice, hotel and blacksmith shop form the town which stands in the midst of untold wealth, while each succeeding year finds its old '49 miners getting scarcer and poorer.

ENTOMOLOGICAL SPECIMENS.—To preserve from insect ravages: Place crystals of carbolie acid throughout the cabinets, and the evaporation of the crystals will keep them thoroughly saturated with carbolie acid vapors, which will kill all living insects therein.

MECHANICAL PROGRESS.

An Improved Crushing Mill.

An improved crushing machine for the rapid reduction or pulverization of hard rocks, ores, quartz and other mineral substances for various mining, metallurgical and chemical processes has been designed and is being manufactured by the Savile Street Foundry and Engineering Company, of Sheffield, and it is claimed that it is comparatively independent of massive stone or timber foundation, being self-contained, and that it is subject to no excessive shocks or vibrations as is the case when weighted levers are used to force up the expanding roll, which is the common practice. The pressure necessary for the reduction of any given substance is applied direct through the intervention of india-rubber buffers and washer-plates set up by screws and lock nuts. The pressure may be increased or diminished at will, without stopping the machine; the pressure is rapidly increased as the roll opens, and the closing of the roll is not accompanied by the heavy blow due to weighted levers, whilst the pressure is more constant at all times, and the foundations are relieved of those severe strains due to the rapid rise and fall of the weighted levers, which are constantly altering their position. The rafter-wheel elevator used to return the rejected or coarse material after screening, is constructed entirely of wrought-iron instead of wood as heretofore, and is secured directly to the axle of the driving roll. The arms are made of T-iron bars attached to the center boss and the outer rim which carries the internal lifting buckets. These arms are further stiffened and tied together by a wrought-iron ring midway between the boss and rim. The receiving hopper is of wrought-iron plate, divided in the center, and riveted to angle irons in the corners. The crushing rolls, which are 28 inches diameter by 16 inches on the face, are made of chilled iron, and secured to cast-iron centers by projecting ribs and wooden wedges. The material is fed to the rolls by a rotating screen receiving the stone or ore from a stone breaker. The crushed stuff is passed through a rotating screen with an internal perforated steel drum, surrounded by another steel drum, with holes fifty to the square inch. The outer screen is perforated to suit the desired comminution. The framework is of cast iron, and carries all the gearing and shafts in adjustable brass-lined bearings. A massive fly-wheel driving pulley maintains a more even and constant speed of the belt. The belt speed is reduced seventeen times on to the driving roll.

A New Musical Instrument.

A novel musical instrument called the autophone is manufactured by the Autophone Company, of Ithaca, N. Y. It is quite small and is a wonderfully simple instrument for one that accomplishes so much. It requires no special skill to operate it, and one kind of music may be played as well as another.

It consists of an upright rectangular board, having on one side a bellows, and upon the other a flexible air chamber, communicating with a set of reeds in the upper edge of the board. Above the reeds there is an apertured plate, and each reed has an aperture of its own. Above the plate there is a shaft carrying a series of thin disks, which serve to hold the perforated music sheet down upon the apertured plate. The shaft is pressed down at each end by a spring, and carries at opposite ends toothed wheels which engage corresponding perforations in the music sheet.

The music sheet consists of a strip of bristol board having perforations corresponding to the notes to be sounded.

As the music sheet is propelled by the regular working of the bellows, it acts as so many valves controlling the escape of air from the reeds and thus producing music.

The most remarkable feature of this invention is the regularity and perfection with which the music is rendered. All of the parts are played, and the music is of no mean order. While it is a very amusing thing, it is also of very great utility, for those who are without musical talents can play as well as those cultured in the art, and many who would not feel warranted in purchasing an organ or piano can, at a very moderate outlay, provide themselves with both an instrument and a player. It must also prove of great use in schools and other places, as an accompaniment to singing.

Each instrument is provided with a number of perforated music sheets, and we understand that music adapted to the instrument can be furnished at any time.—*Scientific American*.

AN AUTOMATIC ELECTRIC BELL.—An ingenious and simple apparatus for making a bell ring at any predetermined hour of the day, is described in a recent number of *L'Electricite*. It comprises a lens by means of which the solar rays are concentrated and directed on a metallic strip, which is susceptible of very rapid and great dilatation. The result of the dilatation is electric contact, giving passage to a battery current which rings the bell. Although the sun may be covered by clouds, its calorific power is never diminished so much as not to dilate the strip.

Artificial Hay Maker.

The London *Graphic* says that a successful method of artificially drying hay has been long desirable on account of the excessive moisture in the British Isles. Mr. W. A. Gibbs, of Gillwell Park, Chingford, Essex, a gentleman engaged in mercantile pursuits in the city, and also, we may venture to observe, favorably known among the poets of the day, has also devoted much attention to the hay-saving problem. By slow degrees he invented a really practicable process, which is thus described:

"Streams of hot air from the mouth of a hot blast fan, connected with a portable engine, are directed upon masses of wet hay or grain laid in open troughs, and brought in turn, by occasional lifting of forks, under the direct action of the air. By increasing the temperature of the blast it was found that the drying process could be proportionately expedited. Eventually the scheme was perfected by bringing the hot blast fan to bear upon a shed divided into two compartments by an iron partition, and having a space between the iron floor and the ground. Hot air, supplied from the hot-blast fan by means of a duct from an underground furnace, communicates with 32 conical perforated tubes on the floor, on which are spiked the wet corn sheaves. These tubes of course are used only for grain. The crowning success of the whole process is an atmospheric hoist, worked by the same engine as the hot blast, which elevates and sends up to the top of a stack, 22 feet high, as many as 960 sheaves per hour.

This year, owing to the unprecedented wet summer, Mr. Gibbs' invention has come to the front and been recognized by practical men as one of extreme value. He says, in a letter to the *Field*: "On Tuesday in last week I lent one of my hay driers to Mr. Ashcombe, of Sewardstone, a practical farmer of long experience and large 'holding.' He started it at 9 A. M., and in 10 hours had dried and stacked the produce of 10 acres, estimated at $1\frac{1}{2}$ loads per acre. The total cost was £5 10s. for the 10 acres, rather less than it would have cost to make the hay in the field, had that been possible. The hay was made from unripe, rank, weedy grass which had been perpetually rained upon; Mr. Ashcombe and his men were inexperienced in the use of the machine, and had no help from me; the hay drier was wholly uncovered and heavy showers fell on the hay while it was being dried. In spite of these unfavorable conditions, however, the result was a complete success."

DOUBLE-PISTON STEAM ENGINES.—In the improvements invented by Messrs. Thewlis, of Leeds, one cylinder is employed, and in it two pistons are fitted with their respective piston rods. Pressure is admitted between two pistons in order to give an outward movement thereto, the return motion being obtained by admitting pressure on the opposite side of each piston. The crank shaft is connected direct with the piston rod of the nearest piston, and long rods in connection also with the crank shaft are attached to the outside cranks on the same, and coupled to a crosshead on the end of the piston rod of the other or opposite piston. Each piston rod, although moving in contrary directions, tends to give a rotary motion to the crank shaft, the cranks on the shaft for the nearest piston and the furthest piston being opposite to each other. The means for removing the slide valve for admitting the pressure may be of ordinary construction and actuated by some suitable moving part of the engine. The above described arrangements or improvements are applicable not only to stationary, but also to locomotive engines, and by the application thereof higher speeds can be obtained; at the same time a great saving of fuel is effected, and the engine is much less expensive in construction.—*Mining Journal*.

GRINDING WHEAT BY GROOVED ROLLERS.—A German correspondent says the grinding of wheat by grooved rollers is getting more and more preference over the millstones everywhere where hard wheat is to be had. This is also the case in the United States, where in Minneapolis and Milwaukee, millers are going in heavily for the roller system; but for the breaking of wheat, grooved chilled iron rollers will take the lead over other materials. Our correspondent continues: "The new mills of Governor Washburn, that of Messrs. J. A. Christian & Co., of Mr. Archibald, in Dundas, and quite a number of other mills in Minnesota and Wisconsin, are being erected on the pure Hungarian roller principle from the beginning of the grinding process to the end. I am fully convinced that in the next decade the Americans will be at the head of all milling communities, for even the Pesth mills, although their system is very highly developed, are far behind the Americans, with their mill arrangements, their labor contrivances, and their finely-finished machinery."—*Cor. London Miller*.

IMPROVED BICYCLE.—The latest novelty in bicycle appliances is a contrivance known as "The Encyclopedian Accelerator," invented and sold by Messrs. Pimtis, of London, England. The proprietor claims that by the use of their patent a bicyclist is capable of traveling at the rate of at least 20 miles an hour with no more exertion than riding 10 miles on an ordinary machine. Another feature of it is that hills are more easily ascended, and riding against a strong wind is rendered a pleasure, in place of what, to an ordinary driver, is very fatiguing. Three stoutish rods are fitted inside the driving wheel by means of a brass collar clamped on the spin-

dle. These rods are screwed down into the collar, and extend to within 12 inches of the rim of the wheel. At the end of each rod is fitted a diamond-shaped piece of lead, weighing about six pounds, secured by a nut; it thus depends on centrifugal force for its power.—*Design and Work*.

SCIENTIFIC PROGRESS.

Edison's Electric Light.

The methods and steps by which Mr. Edison claims to have accomplished the undertaking that had its inception in the electric shops in Ansonia, Conn., is now for the first time made public.

When Mr. Edison received from Ansonia the Wallace dynamo-electric machine, or the telemechan, as Mr. Wallace calls it, he at once began his experiments. The amount of power he recovered in the second machine was so incommensurate with the original power applied to the first machine, and transmitted by a wire, that both machines were cast aside. Then Mr. Edison experimented upon the Gramme, the Brush, and the Siemens machines. These were better, but still the loss of power was excessive. Mr. Edison at once left the beaten track upon which scientists have been toiling for years with unvarying results, and struck out into fields altogether new. Instead of exciting the field magnet by the current from the armature, Mr. Edison charges the field magnet by means of a separate machine. The batteries of these generators are charged by means of a Faradic machine. It does not require more than a minute to charge the immense magnets. The internal resistance of the armature is only $\frac{1}{2}$ ohm.

Mr. Edison's new generator differs essentially from the Gramme, Siemens, Brush and Wallace machines. The field magnets are about 54 inches high, and weigh 1,000 pounds. The magnet cores are of wrought iron. They are 6 inches in diameter and 36 inches long. They are mounted upon heavy cast-iron blocks, 10 $\frac{1}{2}$ inches high and 9 inches wide and are connected at the top by a wrought-iron yoke six inches high and seven inches wide. The cores are wound with three layers of No. 10 cotton-covered wire, the ends of which are connected with binding posts on the base of the machine. The two blocks upon which the cores rest, as well as the bearings of the armature, are supported by a cross-shaped brass casting.

The armature, revolving in a cylindrical space between the poles of the field magnet, consists of a wooden cylinder mounted on a $1\frac{1}{2}$ -inch shaft and having attached to its ends soft iron plates, between which are several layers of No. 20 soft iron wire wound circumferentially. Outside of the iron disks there are vulcanized fiber disks having their peripheries notched to receive the several coils of insulated wire wound lengthwise on the cylinder and connected with copper bars of the commutator cylinder. The field magnet is charged by the aid of a separate machine.

Thus, as it may be seen, Mr. Edison began at the foundation. At first he hoped that the machines already in the market would at least furnish him with sufficient power, and he so expressed himself at the time. His hope proved fallacious. The loss of power was altogether too great for economy. In his new machine Mr. Edison says he recovers 95% in his second machine of the power applied to the first.

After completing his dynamo machine, Mr. Edison began to work upon his electro-motor, for without some kind of a measure he could not tell how much of the electric current was expended at any one point. This was soon done. For nearly eight months he has been experimenting upon the little contrivance that is to furnish the light. First it was made to consist of a small platinum spiral without covering. This would not do, because after the current has been withdrawn oxidation to a greater or less degree set in. Then he made a composition, with lime as a base, and with this he covered the spiral. It was transparent but had defects. Finally he hit upon the expedient of completely covering the platinum with a small glass globe filled with oxygen gas. The globe being air tight there could of course be no combustion. This gave the inventor great satisfaction, but still he experimented, and found that the gas was unnecessary and troublesome in charging, and he rejected it, but retained the sealed globe. Then came the difficulty of preventing the intensity of the current from fusing the platinum. This problem, which has puzzled electricians ever since the first experiments in this direction, was met. A solution was found, after great labor and almost innumerable experiments, by an ingenious device. It is well known that the fusing point of platinum is greater than of any other metal. That is to say, if the temperature be raised about a series of metals, each piece of which is of the same size, the platinum will go last; but a heavy piece of brass, for instance, will stand a greater heat than a piece of platinum one-twentieth its size. This knowledge was made use of by Mr. Edison. In each globe he places a block of brass. When the current is intensified to such an extent as to imperil the existence of the spiral, a brass block immediately underneath expanded by the heat presses upon a lever which connects the shunt with the main line. Now, platinum offering great resistance to the current, and cop-

per of, which the shunt is made, offering very little resistance, a certain portion of the current is at once diverted from the spiral, passes along the wire on the circuit, and is thus prevented from accumulating.

Platinum is very expensive now, an ounce costing in the market between \$7 and \$8. Nevertheless, the spirals, which furnish the illumination through incandescence, are so small that it is thought they will not cost more than fifty cents apiece. The company propose, however, to make the fixtures a part of their plant. Platinum, which comes almost exclusively from Russia, is said to be monopolized by two English firms, who fix the price to suit them. Mr. Edison has had pieces of native ore shown him that was mined in the West, but no considerable quantity has been found.

Photography by Gaslight.

It has often been a subject of comment that while other arts have steadily advanced in development and kept gradually approaching perfection, and in some instances reached it, the art of photography has remained at a comparative standstill. The fact that artificial light has just been called into requisition with the most successful results in connection with it will, therefore, go a great way to remove that apparently well-founded reproach. Experiments in photography by gaslight, by means of the patent burner invented by Mr. Wigham, of the well-known firm of Messrs. Edmundson & Co., of Capel street, Dublin, were made last evening at Mr. McFarland's studio, 79 Grafton street, and certainly they must be described as highly satisfactory in every respect. The idea of utilizing gas in this way originated with Mr. J. McFarland, who, as a practical photographer, has studied every branch of his profession with a closeness and an intensity of interest almost bordering on enthusiasm. The Dublin Alliance Gas Company are also entitled to a share of the credit due to the discovery, for it was by attentively observing the great illuminating power of the lights placed in front of their office in Grafton street that Mr. McFarland's inventive genius was turned into that groove of thought which led to the application of gas to such a useful purpose. Mr. McFarland felt, as everybody in his line of business must feel, how seriously the fickleness of sunlight affected his daily receipts, especially in the winter season. He accordingly placed himself in communication with Messrs. Edmundson & Co., and the adaptation of Wigham's patent burner as an efficient substitute was soon arranged. The appliance is easily described. A truncated cone, containing about 45 ordinary gas burners closely packed together, is placed within a large circular reflector. This cone is surmounted by a false funnel, which, while fire-proof, creates a powerful draft. The gas is conducted into the burners through a pipe leading from a carburetor, where it is previously purified, so that when ignited the flame is intensely white. In its passage through the carburetor the gas becomes charged with carbon, and charged increased in illuminating power. The ordinary gas supplied in Dublin is equal to about 16 candles, and by this simple process it is rendered equal to 32 or 33 candles. The saving thus effected in consumption is so considerable that the quantity of gas consumed on "a sitting" is computed to cost a fraction of a penny. The reflector, which is adjusted to turn in any direction, of course is used to cast the light on the face of the sitter, and as the full flame is only required during the brief period of "exposure," as it is technically termed, the waste of gas is inconsiderable. The burners employed are the same as those used in the Howth lighthouse, though of miniature dimensions, and the 45 are equal to about 1,000 candles. By means of this novel contrivance cartes can be taken at any hour, night or day, which is unquestionably an incalculable advantage both to the artists, who will put money in their purse thereby, and to the "photo-loving" public, who will be spared much anxiety and annoyance. The likeness produced by gas-light is quite as good as those produced by the aid of the natural luminary. Another novel idea in this connection must be mentioned, as it bids fair to introduce a little revolution in an important branch of industry. Mr. McFarland is now enabled to produce Christmas and Easter cards, which are veritable photographs, embellished with devices suitable to the particular season. When people receive the "counterfeit presentment" of their friends indelibly imprinted on the customary card, with which we are all so familiar, they are likely to treat the "delicate reminder" with more ceremony than it usually receives.—*Dublin Paper*.

THE ELECTRIC LIGHT IN THE GERMAN ARMY AND NAVY.—The "Year Book for the German Army and Marine," states that the electric light has been employed for military and naval purposes; among others for lighting up the ground lying in front of a besieged fortress, for the illumination of ships at sea, and notably for carrying on work under water. A transparent bell with an electric lamp has been immersed to a depth of 60 meters, while a magnetic electrical machine placed at a distance of 100 meters has been able to maintain a strong, unbroken current, so that a brilliant light was maintained for a long time. The same authority states that experiments are now in course of being carried out for the purpose of testing how far the electric light can be usefully employed in marine warfare, and especially as a defense against torpedo attacks.—*Gaslight Journal*.

Mining Share Market.

The stock market has taken a very decided tumble this week, and the shrinkage in "securities" has been somewhat disastrous. The break has been aided, if not caused, by the proposed shutting down of the Savage and consequent expected flooding of the Halo & Norcross—elsewhere alluded to. Our stock tables will give the details of decline in prices.

On the Comstock the situation, aside from that in connection with the Savage and Halo & Norcross, remains unchanged, and there is no new feature along the lode worthy of special comment, except along the Hardy vein in Ophir, and in the Union-Mexican vein from the 2,000 level, where improvements are noted. In some of the mines less than the usual amount of work is being done; but these mines are mostly those south of the middle.

We give in another column the elections of several mining companies.

Since writing the items in other columns, as we go to press a compromise between Hale & Norcross and Savage managers is announced to have been effected, the Savage to keep its pumps running and half the expense to be paid by the Hale & Norcross.

The North Con. Virginia Mining Company have petitioned to be allowed to disincorporate.

Meetings and Elections.

OPHIR M. Co.—Dec. 17th. Directors: C. L. Weller, Geo. Wallace, C. H. Fisk, R. H. Follis, J. N. Dohinson, A. K. P. Harmon and C. O'Connor. The reports of the President, Col. Weller, and Superintendent Patten give, to quote the President's language, "good reason to believe that the company may enjoy a long period of dividends." The report of C. L. McCoy, the Secretary, shows the following receipts and expenditures: Cash balance on hand December, 1878, \$17,503.38; assessment, balance of No. 34, \$2,700; hollion yield for the year, \$1,283,246.07; hollion sales, \$735.01; product of ore purchased, \$22,055.65; received from other mines for labor, material, power, hoisting and pumping, \$223,019.10; rebate on freight, \$457.64; total receipts, \$1,549,716.85. Paid for salaries and wages at the mine, \$535.282.75; supplies and miscellaneous expenses, \$404,246.84; reduction of ore, \$172,575.45; purchase of ore, \$22,055.65; discount on hollion, \$111,720.79; freight on hollion, \$5,245.99; taxes, \$23,556.42; water rent, \$13,200; office expenses, San Francisco, \$8,446.18; Virginia, \$882.66; assaying, \$3,704.37; interest and exchange, \$3,049.47; legal expenses, \$6,262.45; insurance, \$2,400; surveying, \$1,200; assessment expenses, \$195; dividend No. 23, \$1,000,800; total expenditures, \$1,414,824.02. Bullion on hand, \$59,952.04; cash on hand, \$72,151.30; cash with Superintendent, \$2,789.49; total amount on hand, \$134,892.83.

GOULD & CURRY.—Dec. 15th. Directors: W. S. Hobart, A. B. Hull, William S. Lyle, A. Hayward, William Kohl, S. Heydenfeldt and Robert Sherwood.

MR. DIABLO M. Co.—Dec. 15th. Directors: H. H. Allen (President), N. C. Paddock (Vice-President), J. W. Shaw, M. Hubbard, C. N. Shaw (Secretary).

IDAHO M. Co., of Grass Valley, Dec. 15th.—Trustees: Edward Coleman (President and Supt.), John Polgrave (Vice-President), John C. Coleman (Secretary), Geo. W. Hill (Treasurer), M. P. O'Connor.

Bullion Shipments.

Since our last issue, we have noticed the following hollion shipments:

Ophir, Dec. 9th, \$37,145.73; Northern Belle, Dec. 10th, \$6,034.42; Con. Virginia, Dec. 11th, \$45,834.57; California, Dec. 11th, \$19,450.10; Alexander, Dec. 12th, \$6,212.68; Gila, Dec. 13th, \$1,162.18; Belle Isle, Dec. 15th, \$4,000; Navajo, Dec. 15th, \$6,700; Paradise Valley, Dec. 11th, \$4,492.34.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

GOVERN.—Amador Dispatch, Dec. 13: The Govern mill has started up again, and is now at work crushing Zeile.—The boilers, drums, stacks and other heavy articles for the machinery of the Zeile mine have arrived in town.

BUTTE HARRIS.—At this mine one of their large pumps got out of order down in the shaft last week, and being unable to get the water out in order to repair it, they solved the problem by sending below for a couple of professional divers, who went down in the mine last Sunday and succeeded in getting it in working order again.

ST. LOUIS.—Amador Ledger, Dec. 13: A parcel of 50 tons was crushed at the Amador Con. mill, at Sutter Creek, lately, which yielded \$500. Ten dollars per ton leaves a handsome margin of profit. The Amador Con. mill, at Sutter, is expected to start on rock from the new shaft about the first of next month. The Clark mill, near Oleta, commenced operations on custom rock on Wednesday. A full head of water is running in the Puritana ditch, and the gravel claims in the vicinity of Oleta are preparing to start. The Amador Gravel company, whose claim is two miles from Jackson, have just cleaned up. We are informed that \$1,600 was the product, a very good yield considering the washing done.

PLYMOUTH.—Our mining prospects in this section were never better. It is now thought by good, practical miners that the coming season will open up many of our mines which have been lying idle for years for want of capital to work them.

BUTTE.

BANNER MINE.—Butte County Register, Dec. 12: This old mine, after lying idle for 20 years, has again been put in working order, and the first clean-up for five days' work showed an amount equal to \$3,500. The opening of these mines will contribute largely to the prosperity of Oroville.

CALAVERAS.

WEST POINT.—Cor. Calaveras Chronicle, Dec. 11: The Champion's new hoisting works are about completed, and will soon be in motion. Their mill is running steadily on good quartz. San Francisco parties and experts are at present examining the Lone Star and feed & Hillary mines, and I believe so far are favorably impressed. The granite casing of the Tom Pine mine, crushed at Carlton's mill recently, paid \$50 per ton, while the quartz paid \$23 per ton. Henry's mill is at present engaged crushing rock for Tuck & Co., which will average \$50 or \$60 per ton.

MILL STARTED.—The mill at the Safe Deposit gravel mine, which was moved lately to facilitate operations, started up Tuesday of this week. The new tunnel is completed and any amount of fine-looking gravel is being taken out.

DITCH BROKE.—The Canal Company's ditch broke again Tuesday, causing a failure of the water supply for a couple of days.

CONTRA COSTA.

PROSPECTORS.—Antioch Ledger, Dec. 13: The work of extracting and shipping coal from the Empiro mine continues, and the owners, Messrs. Judson, Belshaw and Rouse, have found it necessary to put in an additional engine for hoisting two loaded cars at once. The mine is looking more favorable as it is opened at a greater depth. They are now working on the mine and the 1200 level, and the incline has reached the depth of 1,500 ft. The company is shipping about 200 tons of coal daily.

EL DORADO.

A NEW MILL.—El Dorado Democrat, Dec. 13: Twenty carpenters, and a proportionate number of other hands, have been at work on the new mill and other buildings in course of erection by the Placerville Gold Quartz company. These buildings, when completed, will rank with the most substantial and convenient mining improvements in the State.

LAKE.

QUICKSILVER.—Calistogian, Dec. 13: The Great Western Quicksilver mining company, of Calistoga, have declared a dividend of 25 cents per share, payable at once. This indicates that the mine is well managed, thus proving a source of revenue to its stockholders, of whom, on account of the large number of shares held by each, there are very few. During the week ending with Tuesday, Dec. 9th, \$8,490 pounds of quicksilver were shipped from Calistoga to San Francisco.

LASSEN.

HAYDEN HILL DISCOVERIES.—Review, Dec. 13: There have been some recent discoveries at Hayden Hill. A short time ago Farling & Harvey struck a vein of decomposed quartz, which was fabulously rich. In a space 20 ft deep by 20 ft in width, they extracted over \$5,000. They are now down about 50 ft, and the ledge proves to be a last-ling one. In the Brush Hill mine, owned by Harbert & Hoes, they have a shaft 100 ft in depth. On the 60 level there is a drift of 830 ft, and on the 100 level another drift of 110 ft. Hopkins & Co. have sunk to a depth of 150 ft, and have taken out considerable bullion. Three quartz mills are now in operation—the British Hill mill with 10 stamps, the Providence and Golden Eagle mills with five stamps each. The main lead averages about seven ft in width, and pays from the top down.

MARIPOSA.

THE HITE MILL.—Mariposa Gazette, Dec. 13: Hite's new addition of 20 stamps (making a total of 40 stamps) to his quartz mill is said to have started up on Thursday last. The South Hite company are sinking shafts and running leads, and are said to have an excellent prospect before them. They will build a mill in the spring.

MONO.

OPERATIONS IN BODIE.—News, Dec. 14: The weather during the earlier part of the week retarded surface operations to a considerable extent. Operations in the district are steadily expanding. Among the notable improvements projected may be mentioned the King Bee, on Monday sinking of a new double-compartment working shaft will be commenced, and the erection of steam hoisting works will speedily follow. The new shaft house over the South Noonday is rapidly nearing completion. At the Jupiter the pumps and new machinery are being run up to the last as possible. The new pump for the South Bodie will soon be along. If about one week the Noonday mill will be ready to begin crushing ore; and the pumps are nearly ready to start in the mine. The Standard mill cannot be started before January 1st, and it will be nearly a month later before the Bulwer-Standard will be completed. In the way of mine developments, the Belvidere people have cut a fine ledge of enormously rich ore in the shaft. In the Con. Pacific, the showing made during the past week has been flattering. The existence of a bonanza has been actually demonstrated in the Bechtel; but a mill must be built and a new shaft sunk before the stockholders can realize the dividends. The Boston Con. has been proving itself a valuable property of late, while the Queen Bee, near by, looks very encouraging. Several mines, such as the Bulwer, Goodshaw and Mono, have got their pumps to working. Notwithstanding the stoppage of the Standard mill, there is not likely to be any falling off in our monthly bullion product.

KING BEE.—In the King Bee a new double-compartment shaft is to be sunk to test richness and extent of ore veins. The mine has lately been much improved by New York parties.

BUWER.—Work has been resumed on the old Rustler by reopening the old shaft.

JUPITER.—Pumping machinery nearly all on ground. At the 500 level they are now timbering portions of the main south drift. The east crosscut from this drift out the east wall six ft. A crosscut was then started west,

and is now in 43 ft with favorable indications. It is proposed to run this crosscut the entire width of the company's ground, and from the favorable indications important developments may be made at any moment.

BELVIDERE.—This valuable property again gives promise of soon being a bullion-producing mine. The late strike of a three and one-half foot ledge at 352 ft in the shaft, or 62 ft below the 300 level, is most encouraging. Assays taken from the bottom of the shaft at different points, to get a fair average, went \$34.50 to \$96.00.

ADDESSA.—The drift on the 460 level looking well and producing the usual amount of good ore. Work suspended for the present on the 300 level.

DELAWARE.—The company has concluded to open a station and drift from the 475 level, this arrangement allowing them a 25-ft stump, and will be 225 ft below the upper ledge, a very fair distance for cutting and testing the ledges cut at the 250 level.

MARYLAND CON.—Bodie Chronicle, Dec. 13: The new ledge struck on the 4th inst. yet continues to increase in richness, assays recently made showing from \$745 to \$108 per ton.

CONNECTION.—Connection has been made on the 400 level with the Bodie, thus insuring perfect ventilation. The work is being confined to sinking.

TOHA.—Main shaft 700 ft. Vein in bottom of shaft is improving as depth is attained.

NEVADA.

PLANET GRAVEL MINE.—Grass Valley Union, Dec. 14: The location from the end of the tunnel, in the Planet gravel mine, has been sunk nearly 150 ft, all the way through gravel which prospects well in gold. The bed rock still continues to pitch, and the bottom of the channel has not been reached or its width ascertained. The engine does the hoisting and handles the water in the mine easily, with plenty of power to spare. The gravel taken out is all saved for washing, but no regular washing will commence until the ground is sufficiently opened to admit of the steady extraction of gravel. The character of the gravel improves as the incline descends more toward the bottom of the channel.

DEWEY GRAVEL MINE.—This mine, on the Steep Hollow side of the Bear River ridge, and nearly opposite the Planet ground, is being rapidly opened up, and preparations making for washing gravel by the construction of gravel dumps, and the necessary buildings, so as to admit of regular operations through the winter months.

PENNSYLVANIA QUARTZ LODE.—This quartz lode, located just beyond Ophir hill, on the head of Mary's ravine, is now being prospected by a shaft sunk near the old reservoir. The shaft is down 30 ft, at which depth the ledge shows a width of four ft.

BULLDOZER.—Nevada City Herald, Dec. 11: J. J. Rogers, Esq., reports work as progressing satisfactorily at the Bulldozer mine. The owners are taking out another crushing of rock. The last crushing paid about \$14 per ton.

NORTH BLOOMFIELD.—Cor. North San Juan Times, Dec. 13: The Bloomfield company are washing steadily, and are receiving handsome returns. This section of country is one of the richest in the State, and has a bright future. The inhabitants look cheerful and have "fixed up" to stay. The Dodge company are employing about 100 men, and pay cash every month. The mine is on a paying basis, and a tunnel is about to be run to drain the channel, which has proved to be rich and extensive.

ESOCOT MEX.—Nevada Transcript, Dec. 17: Washing was stopped Monday at Sargent & Jacobs' hydraulic claim, Ophir hill, on the water supply. The water supply. The first storm that comes will start the monitors again. Mr. Jacobs says that scores of men apply to him every week for work, but that already he has every position filled and all probable vacancies for some time to come are spoken for.

ANALANTE.—The Adalante company have determined to sink an incline on the north side of the hill, in hopes of opening up the rich ledge of heavy sulphureted ore. The shaft heretofore sunk to the depth of 118 ft at the center of the hill will be abandoned for the present.

QUARTZ MINING TREAS.—The Murchie is steadily producing good ore, and extensive improvements are being made in the way of smelting works, etc. The Providence drain tunnel is in a distance of between 1,500 and 1,000 ft. The Merrill has a ledge of heavy sulphureted ore. Hoisting and milling rock going on steadily. The Wyoming has a good ore body. The new and long drain tunnel is proving a great advantage in working the mine. The tunnel on the Champion, through which the company can work several ledges, is approaching completion. A clean-up of 14 tons from the Davenport, last week, gave a yield of 105 ounces of amalgam, worth about \$550. The old Eastern mill, which was revived with the aid of Eastern capital. The hoisting works on the Mt. Auburn claim are nearly completed. The Bulldozer shaft is down 30 ft. Cravings of the rock have yielded \$10 per ton. The Crosby and Olive mine on Gold Flat is turning out some very rich ore, there now being about 60 tons at the mill. The new hoisting works of the El Capitan have started, and the shaft down ft, was a 22-inch ledge at the bottom. The new ten-stamp mill of the Nevada City mine is running nearly to its full capacity the greater part of time. Work in the gravel mines in the district is being industriously prosecuted.

PLACER.

MOUNTAIN GATE.—Placer Argus, Dec. 13: The Mountain Gate mine, at Danamass, is getting rich pay dirt at present. Thirty carloads recently taken out averaged \$3.80 per carload. Twenty-three men are employed in the mine. The contract for running an upper air shaft 250 ft long was to have been let last Sunday.

DIVINE TREAS.—Placer Herald, Dec. 13: The mining season has begun with a fair upturn in the Forest Hill divide. Most of the ditches already having considerable water in them. Pond & Constable, at Todd's Valley, are running with about 500 inches, and the prospects are that this will be much increased by the late storm. They will put off a blast of 18,000 pounds of Judson powder during the coming week. The Dardanelles mine is running one pipe with a capacity of 150 inches, night and day, and will start up another in a few days. Two more blasts will be fired during the coming week. About 9,000 pounds of Judson powder will be used in each. An upraise from the end of the Vigilance tunnel in this mine has been run into a channel of rich pay gravel.

PLUMAS.

ON THE DIVIDE.—There is a good prospect of quite lively times the coming spring at the mines on the divide between the Meadows and Indian Valley. These mines are immediately on the line between Plumas and Lassen counties. Water is obtained only by the melting of the snow in the spring.

SAN DIEGO.

JULIAN AND BANNER DISTRICTS.—San Diego News, Dec. 13: The Hubbard mine is now down 365 ft. On the dump are 200 tons of ore expected to yield \$20 per ton. There is talk of work being resumed on the old Washington, which was a discovery claim of the district. The Newwall Jackson mine, which is some eight miles from Julian City, and which was worked for some years and then shut down, is to be worked again. A new shaft is to be sunk. Messrs. Farley, Clark & Co. hope to develop a good paying mine this time.

SIERRA.

MEXICO TREAS.—Cor. Mountain Messenger, Dec. 13: W. M. Messrs. Ophir hydraulic ground, Muganville, has done well this year, with a good prospect of better triumphs next season. William Frank has bought the old claims of Conrad & Pearson, Marysville, and will do his full share in the good work as soon as water comes, as his iron pipes are all laid and in good condition. David Richards is already fixed in Saw-mill ravine to commence hydraulic mining as quick as the water comes. He made an excellent clean-up on old abandoned ground this year. F. Blake has been washing some bedrock. Last year he realized good pay from the old ground purchased of Parks and Thatcher. The Colestiale, who bought Harry Baker's drifting and hydraulic claim, are washing up their drift dirt now, and on advent of water season will begin hydraulic.

SISKIYOU.

DRIVER DIRT.—Yreka Union, Dec. 13: During the sudden rise of water in the Klamath river last Thursday week, the water broke through the dam of the Pacific mine and filled up the claim, which of course stops all work for this winter. The wheels were carried away but the shafting, pumps and derrick were saved. Some of the tools were buried in the claim, but most of the property was saved, and the tools buried in the claim will be got out when it is opened next spring.

TULARE.

SEN ROSA.—Visalia Delta, Dec. 12: C. F. Converse has made arrangements with the owners of the Sub-Rosa quartz lead, in Yokoh valley, to sink their incline 100 ft from its present depth, which is now 120 ft. This lead is four ft wide and shows free gold, and should it hold its present size and richness to the depth proposed, it would open up a body of ore that would justify a mill being put up.

TUOLUMNE.

SALE.—Tuolumne Independent, Dec. 13: R. C. Davis and A. Ericson, locators of the Continental, have effected a sale of this mine to parties below for \$10,000. The company have already taken possession and are to commence the erection of buildings preparatory to further developing the mine, under the superintendency of James T. McLean. Never, in the history of quartz mining in this county, has there been so much interest and so prosperous an outlook as at the present time. It may be said to be the dawn of a new era in the quartz mining interest in Tuolumne.

NEVADA.

WASHOE DISTRICT.

OPHIA.—Gold Hill News, Dec. 17: The pumps are running from the 2000 level to the Suter tunnel level and they are being extended down to the 2300 level and will then be continued to the 2500 level. The main incline continues in very fine-looking vein material containing considerable quartz giving low assays and dipping east.

MEXICAN.—The joint Union winze from the 2000 level is down 235 ft in a vein formation carrying clay and quartz of low grade, which promises well.

CON. VIRGINIA.—On the 2120 level a drift has been started west from the main Southwest drift to explore the ground lying west of the old No. 1 winze, and is making good progress.

UNION CON.—The stopes on the 2400 level continue their usual yield and the work of extending the sill floors along the incline, east 10 degrees south is progressing favorably. The yield of this level is only limited to the floating capacity of the Union shaft while other work is going on through it.

CALIFORNIA.—On the 1750 level ore is stopped from the south drift from the bottom of the winze from the level above. The crosscut east from the main drift north on this level continues in a favorable vein formation.

STEVENS DISTRICT.—The work of putting in the main chord of the surface bob is well under way, and the engine will be placed as rapidly as possible. The machinery is arriving rapidly and will all be on the ground as fast as it is needed.

FORAN SHAFT.—The bed plates of the pumping engine are being placed. The cooling pond is completed and the work of putting in the pumps has been commenced.

SILVER STAR.—The east 1720 level of the 2300 level is now in 108 ft, the face in a soft vein formation of clay, porphyry and quartz, the latter giving low assays. Work has been resumed in the north lateral drift on this level, and it will be pushed on for a main thoroughfare on this level.

HALE & NORCROSS.—During most of the past week all energies have been directed to preparing the mine for the anticipated flooding from the Savage. The loose ground has all been caught up, and now the work of sinking the winze on the south line will be pushed vigorously.

SOLIN SILVER.—The crosscut east from near the north end of the tunnel has some 30 or 40 feet farther to go, in order to intersect the excellent ore vein known to exist in that direction, and which was cut into by the other east crosscut farther south.

BECHTEL.—After placing the pumps at the 2300 and the 2500 level, work was resumed on the 2120 level.

SAVAGE.—No work doing in this mine except repairing and putting in order the connection with the Hale & Norcross on the tenth level at the head of the incline. This is needed for ventilation and for a passage-way between the two mines. Orders have been received to continue pumping full till further instructions are given.

VIRGINIA WINZE AND CURRY.—The new joint shaft is encountering plenty of water, which requires the full force of the pump to keep down.

NORTH BONANZA AND FLOWEY.—The station at the 000 level has been completed, chutes constructed, and a drift started to open up the ledge on this level.

BEST AND BELCHER.—Connection has been made between the drift north from the bottom of the Joint Con. Virginia winze and the drift south on the 2150 level of the Con. Virginia mine.

JULIA CONSOLIDATED.—Preparations for the resumption of work on the 2000 level are going on, that level having been freed from the accumulation of water.

SILVER HILL.—A diamond drill has been sent in ahead of the crosscut on the 1300 level 114 feet, and encountered porphyry, clay and quartz, the latter giving low assays.

IOWA.—During the past week the drift running towards the ledge has showed more frequent and conclusive evidences of nearing the vein.

WARD.—The shaft has attained a depth of 1830 feet, and is penetrating a very promising formation.

UTAH.—The balance bob in the main shaft has been completed, and also the third level of the incline.

LEVIATHAN.—The works are shut down and work in the mine suspended for a few days for repairs, and to lay a new foundation under the hoisting works.

BRISTOL DISTRICT.

ITREAS.—Pioche Record, Dec. 13: Work is still in progress upon the cupel furnace, and the smelter and machinery are undergoing a thorough overhauling. The Hillsdale stands third upon the list of base metal bullion-producing mines in the State of Nevada. Real estate has advanced 100% during the past six months. A good deal of prospecting is being done at Blind mountain. The Hillsdale produced \$72,430 on November account.

ESMERALDA DISTRICT.

REAL DEL MONTE.—Esmeralda Herald, Dec. 13: All work at the mine for the past week has been centered in the excavation for the plunger pump, below the 500 level. This excavation is to be 12x14 ft and 25 long. In addition to this it has been found necessary to enlarge the pump compartment of the shaft two ft for a distance of 25 ft above the 500 level. With no accident to prevent, this work will be completed inside of 10 days, when the plunger will be immediately placed in position. The carpenters at work fitting the pump rods together and getting everything in readiness to put them in place.

Notes on Some Undescribed Fishes of the Pacific Coast.

[A portion of a paper read before the California Academy of Sciences, October 6th, 1879, by W. N. LOCKINGTON.]

A few notes upon four probably undescribed kinds of fishes, examples of which have occurred in our markets—fishes, all of them useless as articles of food, either on account of their rarity or of their small size, but interesting from their structure—may prove not uninteresting.

Icosteus enigmaticus.—The first of these has been in our museum some four years, and has been and still is a puzzler. That is to say, it has peculiarities that make it difficult to place it in any of the recognized families of fishes. It has no scales, but there is a row of bunches of prickles along the lateral line, and the fin-rays have smaller prickles set along their sides. The body is exceedingly compressed and thin, the snout blunt, the pectoral fins have a fleshy base, and the caudal rays are arranged fan-fashion, round a fleshy semi-ellipse. The mouth is large, and the only teeth are on the jaws. It must be remembered that many fishes have teeth in the interior of the mouth, on the vomer and palate bones, on the tongue and on the gill-arches in the throat.

Another very obvious peculiarity is the want of consistency in its bony framework. The vertebrae are soft, the jaws and other facial bones are flexible and easily distorted. The only bones possessing the least firmness are those surrounding the brain.

Two specimens of this fish, with a third which differs in some particulars, and is now too distorted to do anything with, were procured in the market by Mr. Harford, and I lately saw a small specimen in the museum of the State University, Berkeley. The last example came from Washington Territory. Prof. Cope saw examples of the fish in Oregon. Most fishes whose habits are pelagic, that is, ocean fishes living in deep water, have softer bones than shore fishes, and it is probable that this fish lives in the depths, and only very occasionally straggles within reach of fishing-nets. Those in our possession came from the deepest water reached by fishermen, and were called "deep-sea fish" by them.

Myriolepis zonifer.—Another rarity, of which I have as yet only seen one specimen, looks at first sight very much like a very young *Jew-fish*, (*Stereolepis gigas*). Like that fish, it has two distinct dorsal fins, and there is considerable resemblance in form, as well as in the scales and teeth.

But a closer examination shows many differences. The teeth, though small and numerous, forming a band of many rows in both jaws, are positively larger than those of a *Jew-fish* of eight times its bulk, and the free edge of the preopercular bone, which is denticulated or toothed in the *Jew-fish*, and in most related fishes, is without teeth or spines. The number of rays in the fins is not the same as in the *Jew-fish*, and the shape of the fins is different.

But the most curious thing about the fish is the great development of its scaly covering. Most fishes have the fins, or certain parts of the head, without scales; but this fish is almost completely covered with rough scales. The jaws, upper and lower, the opercular bones to their edges, even the exposed surfaces of the gill-rays, are scaly. The outer surfaces of the pectorals and ventrals, and both sides of the anal, second dorsal and caudal, are scaly, and even the rays of the first dorsal are not free from scales.

Artedius quadriseriatus.—Among the fishes known as sculpins, is a group of small marine forms, which have teeth upon the inside of the mouth as well as on the jaws, the gill-membranes are united to each other beneath the throat, a band of scales along the body, and a flap of skin over each eye.

A small species belonging to this group occurs with tolerable frequency among the heaps of prawns (*Pandalus danae*) in our markets. As it never much exceeds three and a half inches in length, it is of course of no value as food. The principal specific character of this little fish is that its otherwise scaleless body is traversed by four separate single rows of ctenoid scales, one along the middle of each side, the other pair nearer the dorsal outline. The lower row is pierced by the pores of the lateral line. The preoperculum is armed with a particularly ugly weapon in the shape of a long spine which branches on its upper margin, antler-like, into four or five other spines. It is these preopercular spines, with others upon the top of the head, which cause the sculpin tribe generally to be abhorred of the fishermen.

Odonotopis trispinosus.—Not very distantly related to the sculpins is a tribe of fishes that are covered with bony plates above and below. Some of these have the pectoral fins so much developed that they can spring from the water and traverse the air for some distance—that is, are flying-fishes—but those found on this coast have not this power.

A specimen of a fish belonging to this tribe, differing from any of which I could find the description, has been in our museum for about four years. It came from Alaska. During the present year I have found several other specimens of the same species in our markets, among the

heaps of prawns which furnished the last species.

It is a very small fish, about three inches long, and totally useless for food. On the end of its snout it bears a movable spine, behind these a pair of fixed spines, another pair on the back of the head, and still another on the sides of the snout. There are teeth on the vomer and palate bones as well as in the jaws, and there are no barbels or fleshy processes under the chin. These two last characters separate it generally from its nearest relatives.

About 36 series of rings of plates cover the body between the occiput and the caudal fin, but the first of these covers the upper surfaces only. The front part of the body is eight-sided, the upper and lower sides largest. Behind the second dorsal the upper and lower surfaces come to a point, leaving a six-sided section. The head is much broader than deep, and its under side, in front of the ventrals, is plated with about 27 plates. The two dorsals are very small; the first with four rays, the second with six. At every angle of the body is a row of keels, one on each body-plate, all ending in a spine posteriorly.

I have forwarded full descriptions of these fishes to Prof. D. S. Jordan, for publication by some scientific academy, which, more flourishing than our own, can afford to publish scientific work.

Some months ago I wrote for publication a description of a small sculpin which I named *Chitonotus megacephalus*, the large-headed mailed-back. Since that time we have received the Proceedings of the Imperial Academy of Vienna, and I find that Dr. Steindachner has got ahead of me, and has described the same fish from specimens obtained in Puget sound.

He also gives a figure. From this figure I judge that the form and proportions of the dorsal fin vary considerably. In my specimens the first spine is exceedingly long, the third quite short, shorter than the fourth, and as these two spines are twice as distant from each other as are any of the others, and the membrane between them dips down almost to its base, the fin is practically divided in two.

Dr. Steindachner's figure shows only a slight emargination of the fin, the first spine only slightly longer than the others, and the spines equidistant. Dr. Steindachner places it in the genus *Artedius*, of which we have a well-known species in our bay.

ARTIFICIAL ICE IN SAN FRANCISCO.—Some months ago the inventors of a new process for the production of artificial ice commenced the erection of a building and machinery on Fremont street, near Folsom. The new process has been tested, and it worked to the perfect satisfaction of the projectors. The principle is as follows: In the building are two large tanks fourteen feet long, four feet wide and four feet in depth, each capable of holding a thousand gallons of water. Each tank is divided into sections of five zinc freezing chambers. Some yards away stands the condenser, a large vessel filled with pipes, through which passes a liquid ether. This liquid is condensed and forced by an air pump into the freezing cells, in which a partial vacuum is created. The ether instantaneously absorbs all the heat in the water and passes again in a liquid form into the condenser, where it undergoes the same process, and is returned to the freezing cells as vapor. In about thirty-six hours the water in the tank has turned into blocks of ice which adhere to the edge of the cells, and from which they are detached by forcing hot air into those chambers. Each tank thus turns out from two to three tons of ice. It is curious in the warm atmosphere of the engine room to observe the ice gather on the pipes which conduct the ether to the freezing chambers. The inventors claim that the pressure is much less than in any other process of ice manufacture, and therefore ice can be produced in a warmer climate. An engine of fifteen-horse power with a perpendicular boiler works the pumps.

THE HOTTEST SPOT ON EARTH.—One of the hottest regions on the earth is along the Persian Gulf, where little or no rain falls. At Bahrain the arid shore has no fresh water, yet a comparatively numerous population contrive to live there, thanks to the copious springs which break forth from the bottom of the sea. The fresh water is got by diving. The diver sitting in his boat, winds a great goatskin bag around his left arm, the hand grasping its mouth; then takes in his right hand a heavy stone to which is attached a strong line and thus equipped he plunges in and soon reaches the bottom. Instantly opening the bag over the strong jet of fresh water, he springs up the ascending current, at the same time closing the bag, and is helped aboard. The stone is then hauled up, and the diver, after taking breath, plunges again. The source of the copious sub-marine springs is thought to be in the green hills of Osman, some five or six hundred miles distant.

A NOVEL TRAMWAY.—A tramway has been opened in the German city of Brunswick on a new principle. The rail has no groove. It is laid exactly flush with the road's level, and may thus be crossed at any angle with any description of conveyance without any jar or disturbance. The car is guided and kept in its place on this rail by slight steel studs on the tire of the wheels, which fit into corresponding holes punched in the rail at the distance of every five inches. The invention is that of an English architect.

England Invaded by the Sea.

The sea is England's defence, the watery wall that protects her from hostile invasion; but it is at the same time an enemy and an invader. It has attacked and destroyed large portions of her territory, especially along the eastern coast. In this way certain localities of historical interest have passed away, like the men who made them famous. For instance, the seaport of Ravenspurgh (also known as Ravensburg, Ravenspurn, etc.), at the mouth of the Humber, where Bolingbroke landed in 1399, had been partially ruined by the inroads of the sea before that event, and afterwards disappeared completely. As early as 1346 the merchants residing there removed to Hull, on account of the encroachments of the waters, and the high tides of 1357 and subsequent years swept away nearly all that remained of the town. Few vestiges of the ancient port could have been left at the time of Bolingbroke's landing, and even these must have been lost before Edward IV. landed there, in 1471, after his brief exile in Holland. The sea has continued its work of devastation down to the present time. A fine old cross, which is said to have been erected at Ravenspurgh in memory of the arrival of Bolingbroke, has been several times removed farther inland, to save it from being engulfed. It was first transferred to Kilssea, and again, in 1818, to Burton Constable, whence it was, in 1832, taken to Hedon, some miles farther up the Humber. There it is likely to find a permanent resting-place, as at that point the sea has been making land instead of destroying it. In the time of Edward I. Hedon was a greater port than its neighbor Hull, but the deposits made by the tide gradually filled up the harbor, and now luxuriant meadows are seen where stately ships, laden with the products of many lands, used to ride safely at anchor.

Along this part of the coast of Yorkshire many ancient towns and villages have been submerged. On old maps we may read, "Here stood Auburn, which was washed away by the sea," "Hartburn, washed away by the sea," "Hyde, lost in the sea;" and so with other places, to say nothing of many mentioned in old documents as being on this coast, but of which the very locality has been forgotten.—*Exchange*.

TWO NEW ELEMENTS.—*Silliman's Journal* for November contains an account of the discovery of two new elements by Cleve, which he has named respectively as thulium and holmium. He was led to investigate the earth erbia in which Marignac had discovered ytterbium, and Wilson scandium, in order to distinguish the substance in this earth which gives the red color and the beautiful absorption spectrum to its salts. As the salts of ytterbium and scandium are colorless, the question was of interest to ascertain whether the substance possessing these peculiarities was erbium itself or some new elementary substance. After a large number of experiments, he announces, chiefly on the strength of spectrum observations, the existence of two new elements, as above noted. The name thulium is from Thule, the ancient name of Scandinavia; and that of holmium from the Latin name of Stockholm. Since the announcement of Cleve's discovery, two other observers, Soret and Boisbaudran, confirm the accuracy of his spectrum observations.

A NEW FIELD FOR WATER GAS.—The increase of rabbits in New Zealand has been so great that it has been seriously proposed to introduce the weasel and the polecat to keep down their excessive numbers. An "exterminator," however, has been invented which seems to be effective. It consists of a machine for generating and forcing into the burrows carbonic oxide gas. On reaching the burrows a flexible tube, about five feet in length, is inserted into the hole, and the gas is forced into the aperture. The entrance to the burrow is then stopped, as well as all holes and fissures that can be found. In a few seconds a great hubbub is heard inside, but this quickly subsides. The burrow is dug open after a short time, when the dead bodies of the rabbits are found huddled together in every corner. The exterminator has been pronounced a perfect success.

NEW MOTOR.—The New York *Commercial Bulletin* says: Engineers, marine underwriters and others, to whom a knowledge of the fact has come, are deeply exercised by recent successes in the application of a giant motor obtained from the bisulphide of carbon mixed with petroleum. The patent, taken out by a Pittsburg firm last April, promises to revolutionize machinery motors. The method consists in the transmission of the above chemical agents from the chamber of the condenser to the boiler of the ordinary non-condensing steam engine. The boiler being filled with water heated to about 200 degrees, a pressure as high as 200 pounds to the square inch is rapidly developed from the vapor thus generated, and easily controlled.

TIGHTENING OLD WINDOWS.—Old windows that do not close tightly may be remedied by smearing the edge on which they close with putty, and that of the sash with chalk, and then closing them as firmly as possible. The putty will fill up the crevices, and the excess pressed out at the sides may be removed with a knife, whilst the chalk prevents adhesion to the sash.

Detestable Frauds.

[Br 11—No. 1.]

Verily there is no end to the frauds which are continually being perpetrated upon the unsuspecting public. They constantly loom up and present themselves in as varied disguises as are ever seen at masquerade halls, and are equally varied in character.

The class which we now have to deal with, is the advertising class, who use the newspapers to obtain money by promises of returning from 10 to 50 times the amount sent, in articles of various kinds. We have before us as we write, several samples of these advertisements which have been sent us for insertion in our papers, and to receive in payment for such insertion, in one case a Bible, and in another a revolver. We are not in want of either Bibles or revolvers, and as we know the whole thing to be a fraud we decline to insert the advertisement, preferring to use our columns only for legitimate purposes.

The Bible man in his advertisement describes a "Royal quarto Bible," containing:

The Old and New Testaments, Apocrypha, Concordance and Psalms, nearly 2,000 illustrations, 36 full-page engravings, and 115 additional features, the most important of which are a Bible dictionary, history of the books of the Bible, history of religious denominations, history of the nations, cities, rivers, lakes, birds, beasts, reptiles, insects, trees, fruits and flowers of the Bible, 100,000 marginal references, marriage certificate, family record and a photograph album. Printed with clear, large type, on paper of first-class quality. The work is superbly bound in Morocco, massive raised panel, gilt edge and back, and was sold two years ago at \$15 per copy.

And he further says that for \$1 he will send, postage paid, a copy of the Holy Bible, but he does not say that he will send a copy of the above described \$15 Bible, not he. He may possibly send a Bible, but it will probably be such a one as can be bought at any bookstore for about 75 cents or \$1. It is extremely doubtful, however, if the sender ever hears from his dollar agent.

The revolver man, who by the way is evidently the same person though a different name is given, offers a six-shot revolver free to any one who will send 75 cents for a six months' subscription to an unknown paper. He says:

The famous *American Model*, six-shot bulldozer revolver is made of select metal and is neatly finished. The cylinder revolves when the hammer is raised. Can be loaded in an instant. Just the thing for tramps and burglars.

We do not exactly understand this. Is it possible that he is desirous of obtaining the patronage of tramps and burglars? I would seem so from his advertisement.

It may be that knowing that his revolvers are worthless, he thinks that he will be conferring a favor on the public by supplying tramps and burglars with them.

Several months since a friend of ours received a printed postal card from the East, offering to send a genuine Swiss magnetic time-keeper, warranted to keep perfect time, for the small sum of 60 cents. This was his chance to get a watch he said, and he forwarded the amount to the sender of the card. For about three weeks visions of fine time-keepers haunted his waking and sleeping hours. They haunt him no more. He never more heard of his 60 cents or the watch he was to get.

Another style of advertisement we have received reads that "\$10 to \$500 invested in Wall street stock makes fortunes every month." "Two unerring rules for success sent free." Address, Bimpson & Co., Bankers and Brokers, New York.

This is evidently another of the so-called bucket-shop swindles, which were at one time so numerous in this city. No bankers or brokers of any pretense to respectability would so far debase themselves as to lend their names to any such nefarious transactions. The chances are that Bimpson & Co., are myths after the style of the late firm of Martin Taylor & Co. of this city, who it will be remembered suddenly disappeared, when it was discovered that the firm name was an assumed one, used to give an air of respectability to the swindle. They also made a medium of many a newspaper (not including ours) to perpetrate their frauds.

MOTIVE POWER ENGINE.—An improved motive power engine, working by means of atmospheric pressure under the effect of barometric vacuum, has been invented by Messrs. Plaisance, Mocquard and Emery, of Paris. By means of two connecting rods a shaft receives a rotary motion produced by the action of two pistons moving in two parallel cylinders. Each cylinder is closed at one end, and communicates with an oscillating cylinder in the form of a U, which may be placed either horizontally or vertically. When it is placed horizontally and filled with mercury, as well as the motive cylinder, the piston should be at the end of the fixed cylinder; the oscillating cylinder is then placed in the vertical position, and mercury falls, and the barometric vacuum being produced, the piston pushed by the atmospheric pressure will re-enter the fixed cylinder. The oscillating cylinder then again takes the horizontal position, and the mercury re-entering the fixed cylinder, the piston moves in the contrary direction. The second fixed cylinder is so placed that its piston and that of the second oscillating cylinder are the reverse of the first cylinder. Counterweights equilibrate the weight of the U-shaped cylinder full of mercury.—*London Mining Journal*.

THE ENGINEER.

Tramway Construction.

A paper was recently read before the Manchester Scientific and Mechanical Society, by W. T. Gunson, C. E., in which the writer described a new system of tramways, which consisted in laying down a continuous length of stone sleepers similar to the kerls now in use for footpaths. In these kerls were cut longitudinal grooves one and three-fourth inches deep, three and one-eighth inches wide at the top, and three and three-eighths inches wide at the bottom, thus forming a dove-tailed groove. The bottom of groove was covered by a one-fourth inch layer of Limmer, Seyell, or other natural rock asphalt, by which means a perfectly even, solid and elastic bed was obtained, upon which to rest the rails and the joints between the sides of the rails, and the sides of the grooves were filled up by a fusible mineral cement. As the rails were rolled on the sides with a splayed foot and groove, they were thus so firmly fastened and embedded in the sleeper as to render any other fastening unnecessary, but if required, they could, in addition, be secured in the ordinary manner by a strong coach screw into a wooden plug, by a bolt and nut, or a gib and cotter. At the junction of the rails, a quarter-inch iron plate, eight inches long, was inserted under the joint, and lead was run in for a similar length, thus making the rails perfectly immovable.

Mr. Gunson claimed for this system that it avoided all the well-known disadvantages of those at present in use—that vehicles of all descriptions could use it, and that whilst the cost of laying down was much the same as other systems, the cost of maintenance was considerably less.

In the course of the discussion, the Chairman observed that although much had been done in effecting improvements in tramways, a great deal yet remained to be done, and they would not arrive at perfection until they got tramways or roadway upon which every description of vehicle could travel. He had no doubt they would get it some day, and he hoped they would never rest satisfied until they did. The members generally condemned the systems of tramways at present in use.

The Hudson River Tunnel.

Since the resumption of work upon this undertaking, by reason of the recent removal of legal obstacles, considerable progress appears to have been made. On the Jersey City side, the shaft at the foot of Fifteenth street has been sunk to its entire depth, 65 feet, and the horizontal drifting of the tunnel proper will shortly be commenced. It is contemplated by the Tunnel Company to work from both sides of the river so soon as the shaft on the Jersey side has been made perfectly clear. The shaft on the New York side will be located at the foot of Morton street. When fairly underway, it is announced that the Tunnel Company intends to prosecute the work day and night without intermission, with the expectation of completing the work within two years.

The published accounts of the exact position of the tunnel when completed afford us the following information: The entrance to the tunnel on the Jersey side of the river will be from the corner of Jersey avenue and Fifteenth street; to extend thence to the Hudson river, about 3,400 feet; thence under the river, curving five degrees northward to the New York bulkhead line, at or near the foot of Morton street, about 5,400 feet, thence curving slightly southward about 3,000 feet to a point to be selected by the New York Board of Aldermen. The entire length of the tunnel, with approaches, will be about 12,000 feet, or about one mile under the river and three quarters of a mile on each shore. The tunnel walls will be constructed of brick and cement, three feet in thickness, and will be of nearly circular section, 26 feet in width and 24 feet in height. The interior will be painted white, lighted with gas, and will be provided with a double-track railway of steel rails laid upon a foundation of stone ballast five feet from the bottom. It is believed that the tunnel will be able to afford transit to 400 trains daily.

THE NEW OCEAN TELEGRAPH.—The Franco-American cable, just laid, is owned by French and American stockholders, whose paid-up capital is \$8,000,000, which is soon to be increased by \$2,000,000 more. The cable runs from Brest, France, to St. Pierre, off the coast of Newfoundland, and thence to North Eastham, near Provincetown, on Cape Cod, Massachusetts. The ship *Faraday*, which laid it, will go back and stretch another cable from Brest to Land's End, England, a distance of 200 miles, and next year another from Land's End to St. Pierre, thus giving double communication with this country. The cable is composed of a copper wire wrapped around by 10 others of the same material. These are all hidden away in three envelopes of gutta-percha, and outside of these again is a wrapping of manilla hemp treated with a protecting compound. Over this is a covering of steel wire, which is itself coated with a layer of anti-corrosive compound. It is said to be the strongest and best cable ever laid.

USEFUL INFORMATION.

Silicate Cotton.

One of the most important outcomes of blast-furnace slag is slag wool, or silicate cotton as it is also called, from its resemblance to cotton wool. Silicate cotton is now generally recognized as among the most efficacious of all boiler and steam pipe coverings, but the main difficulty has been to apply it in such a form that the cotton should remain in a compact state without chance of shifting or escaping during repairs. After a series of experiments Messrs. Daniel H. Dade & Co., of London, have managed to overcome the difficulty stated, by applying the cotton, made into mattresses two and three inches thick, to boilers, rendering the shifting of the cotton impossible. For steam-pipes the silicate cotton cement is equally useful, but another and most successful method is to apply the cotton woven with flexible iron wire into long bands which can be twisted spirally round the pipe, an operation which requires little time and no great skilled assistance. When fixed in its place a covering of canvas protects it from injury. Mr. John Alexander, of Glasgow, writes: "I can show anyone anxious to see it, silicate cotton woven with wire on to canvas, and which is much superior for covering to the mattress plan. At the present moment experiments are being carried on to still further utilize the slag from blast-furnaces."

This article is gradually coming into use for a great variety of purposes under the name of "mineral cotton," and it is suggested that caution be exercised in its use, particularly for filling between floors, on account of the sulphured hydrogen developed by the action of moisture upon the calcium sulphide, which it generally contains. Any paint in the room containing white lead is thus liable to become discolored, and even the health of the occupants may be affected. It is well, therefore, to test mineral cotton before use in buildings, for calcium sulphide.

PLUMBAGO AS A LUBRICATOR.—The *Engineer* gives this example of the value of black lead as a lubricator: "A fly-wheel shaft bearing eight inches in diameter and ten inches long carried a load of nearly ten tons. The bearing was supported on a box girder, and was lined with good brass. The engine could not be run, as this bearing invariably got nearly red hot after a few revolutions; various oils, tallow, sulphur and gunpowder were tried with most indifferent success. By using a mixture of tallow and sulphur the engine could be run half an hour at a time, and once or twice has run a whole day, the shaft making sixty revolutions per minute. It was determined to have a new crank shaft with a longer bearing, but as at the last moment the use of black lead and tallow was suggested, a package of the ordinary black lead used for stoves was worked up with some tallow, the bearing carefully wiped, and the grease box on the cap filled with the mixture. The bearing never heated again unless oil was allowed to get access to it. The success of the plumbago as a lubricator was perfect. It should be added to the foregoing that while the principle of lubricating by graphite, or plumbago, is scientifically correct, and has in thousands of instances been practically illustrated, it has been damaged seriously by the use of impure graphite. For perfect success the graphite should be absolutely clean."

DEADENING OF WALLS TO SOUND.—The report of a committee of a Wurtemberg association of architects upon the deadening of ceilings, walls, etc., to sound, gave rise to considerable debate, after which the following conclusions were reached: The propagation of sound through the ceiling may be most effectually prevented by insulating the floor from the beams by means of some porous light substance, as a layer of felt, a filling of sand, or of stone coal dust, the latter being particularly effective. It is difficult to prevent the propagation of sound through thin partitions, but double unconnected walls filled in with some porous material have been found to answer the purpose best. Covering the walls and doors with hangings, as of jute, is also quite serviceable.

GUYARD'S VIOLET.—M. Jos. Depierre has recently given some interesting details on this dye before the Societe Industrielle de Rouen. It is obtained in the following manner: A mixture of sulphate of copper and ammonia is treated with ferrocyanide of potassium. If the precipitate obtained is washed, dried and exposed to a temperature of 338° F., it loses both cyanogen and ammonia, oxidizes and assumes a fine violet color. A higher temperature changes the violet to blue, and finally to a pale green. M. Depierre has found that the color receives caustic lime, chloride of lime, hydrochloric acid or tin salts better than any other violet known.

LUBRICANT FOR WOODEN AND IRON COGS.—A lubricant for iron and wooden cogs, recommended by Bauer as having proved excellent in practice, may be prepared by collecting the oil dripping from the machinery and pouring into it melted waste tallow until it forms a creamy mass, and the mixing with it fine, sifted glass powder. The cogs are rendered hard as well as smooth by the glass pressed into the pores.

DURABLE COATING FOR PRESERVING ZINC ROOFS.—According to a German journal, experience is favorable to the introduction of a considerable amount of copper into oily or resinous coatings for zinc roofs, by dissolving some suitable copper compounds in the oils or varnishes employed. It is said that they then unite more intimately with the zinc surface and resist the greatest variations of temperature without scaling off. In their preparation a copper soap, formed by the precipitation of a solution of a copper salt with a solution of soap may be dissolved in the varnish by boiling, or the solution of a copper salt may be stirred into the Russian emulsion-like train oil pigment, prepared by mixing train oil with a solution of soda or potash, with suitable earth colors, so as to form a thin, liquid water color. A durable black coating for zinc roofs was also published by Fuescher, consisting of a solution of equal parts of chlorate of potash and sulphate of copper in 36 parts of warm water. The black coating formed on the zinc by its use must be washed and then polished or varnished.

HELIOGRAPHIC PRINTING PLATES.—Tako of glue (Kleber leim) 1 kilogramme, allow it to swell for 24 hours in some cold water, and then liquefy the pieces at a temperature of 25° R., adding 20 grammes of potassium bichromate. Pour this solution over a suitable square of plate glass, previously coated with ox gall and provided with a rim of putty, and allow to dry in a dark place. After the lapse of two days the glue tablet can be readily detached. Now place on the smooth surface the transparent negative drawn in bold lines and strong contrast of lights and shades, or made of perforated card-board, and expose to the sunlight for from one to three hours. After the exposure glue the tablet with its back side to a smooth wood block, moisten the face with water, and finally remove by means of a moist cloth all glue not hardened under the influence of light, when the *cliche* will show the drawing in perfect relief with a smooth printing surface. After completely hardening the *cliche* in the light, it is ready to be used in the printing press. Galvano-plastic copies of this plate may also be taken in the usual manner.

RENDERING WOOD FIRE-PROOF.—For the purpose of rendering wood fire-proof, Col. P. De la Sala dissolves carbonate of potash or soda in water, and, after heating to the boiling point, adds hydrate of lime, graduating the strength so that for potash the specific quantity does not exceed 1.6, and for soda does not go beyond 1.5. With this lye all the exposed parts of buildings, vessels, etc., are saturated, while boards, planks or timbers are immersed in it for a period varying from four to twelve hours, according to the depth of the coating required, or the compactness of the fiber of the wood. For fire protection of building timbers Col. De la Sala considers a fire-proof layer one-eighth of an inch in depth amply sufficient. Veneers must be passed through steel rollers immediately after having been operated upon.

GOOD HEALTH.

A Medicinal Tree.

A writer from Paris says, there is a palm tree in South America, *Papaya carica*, which possesses very remarkable properties. Its sap is a very powerful digestive agent. Digestion is a very complex act. Meat is digested in the stomach; fecula, already modified by the saliva, achieve their transformation in the intestines, while fatty matters are only digested in the intestine. Hence, the explanation why some persons can digest meats and eggs without difficulty, while their stomachs are rebellious to feculent and fatty substances. Individuals on the other hand, who cannot eat veal, can partake of fatty preparations and pastry without inconvenience. Thus each organ has its role, and on their state of health depends the integrity of digestion. Inhabitants of cities suffer most from dyspepsia, that is, from an alteration of the digestive ferment. It is to this latter class of sufferers that Messrs. Wurtz & Bouchut have investigated the action of the *Papaya*. The latter gentleman has experimented with the preparation since two years, and with success, in the hospital for sick children. The papaya is more generally known in America as the "melon tree;" the fruit is rose-colored, sweet, and is eaten like an ordinary melon; the trunk and the veins of the leaves contain a bitter, milky sap or juice, which, after a short exposure to the air, emits an odor resembling rotten cabbage. The sap exudes when an incision is made in the trunk; it immediately coagulates, and separates into two parts, a more or less soluble pulp, and a limpid colorless serum. Now if this juice in its natural state be placed in contact with raw meat, fibrine, the white of eggs or gluten, it will soften these substances in a few minutes, and in some hours dissolve them at a temperature of 40 degrees centigrade. Milk is rapidly coagulated by the juice, and its caseine precipitated and dissolved. False membranes from croup, and intestinal parasites, as tape worms, etc., are similarly disposed of in a few hours. If a heefsteak be cut up in morsels, placed in a cancer containing some papaya juice, they will be seen to gradually disappear, to melt away as if they were lumps of sugar. Clearly the papaya contains a ferment resembling that peculiar to carnivorous plants, as the drosera, neperthee, etc. Vegetable pepine is not exactly

a novelty, but that in the sap of the papaya is stronger than what is secreted by the stomach, and possesses this superiority, that it can dissolve nitrogenous matters not only in the presence of a small quantity of acid, but even in a neutral medium, or one slightly alkaline. While weak digestions have reason to rejoice, it is not less important to bear in mind the efficacy of the preparation in the treatment of croup and of tape worm.

Railroad Men and Colors.

A paper on "Libraries of Railroad Young Men's Christian Association," by R. B. Poel, librarian of the Y. M. C. A. of New York city, which was read before the second International conference of Christian railroad men at Altoona, Pa., in September last, contained, in addition to other excellent advice with regard to the collection and management of reading matter for railroad men, the following passage: "The question of color blindness among railroad men is one of vital importance to the great traveling public, one in which personal safety or peril is involved. We know of but two treatises in English on this subject, but every railway library should have one or both. The earliest treatise is by Prof. Holmgren, of Upsala, Sweden, and was published in 1877, entitled 'Color Blindness, and its Relations to Railroads and the Marine.' A translation was published in the report for 1877 of the Smithsonian Institution. Since Prof. Holmgren's work was published we have had Dr. Jeffries' 'Color Blindness, its Dangers and its Detection,' in which he copies a good part of Prof. Holmgren's book; but Dr. Jeffries has made 10,000 tests of his own, of which he gives the results. Those who wish to pursue the study further, in German and French, are referred to Hugo Mangus' 'Histoire d'Evolution du Sens des Couleurs,' 1878 (History of the Evolution of the Color Sense); Herman Cohn, 'Studien ueber Angerhorne Farhenheit, 1879 (Studies Relating to Innate Color Blindness).'"

AMERICAN OVERWORK.—One need not dwell upon the desirableness of calm and seclusion for the production of the best literature. With individuals, as with nations, stirring periods of action are not favorable to idealistic art. There is much unfairness, however, in the blame to which public men in this country are subjected for their overwork. This is rather a matter of necessity than of choice. People in the Old World largely inherit their means and methods from their forebears. New men, even there, often have the habit of overwork fixed upon them by the time their footholds are secured. But the statesmen and thinkers of Europe start with assured incomes more commonly than do our own, and are not forced to earn their bread as they go along. Our Wilsons, Evertses, Curtises, have had to consider first the means of living, and to be statesmen or writers in addition. Our Eastern Brahmins, happily, have had for the most part resources which they have enlarged by the help of such gentle, scholarly pursuits, as the service of a university affords. They have shown themselves quite willing to indulge a spirit of restfulness and calm. So long as Americans who do not inherit estates have the Anglo-Saxon pride and domestic tenderness, they will be tempted to do work elsewhere than in a garret, and rarely be able to drive from their minds the thought of its effect upon an income-paying constituency.—*E. C. Steadman on Bayard Taylor, in Scribner for December.*

MILK DIET IN HEART DISEASE.—M. See, in his book on the treatment and diagnosis of heart disease, regards milk as a powerful diuretic. He does not approve of exclusive milk diet, which, in his opinion, reduces the patient to a state of extreme inanition, but prescribes a mixed milk diet of about two liters and a half of milk per diem added to the patient's usual food. This does not in the least interfere with the diuretic effects of the milk. These effects must not be attributed merely to the water contained in the milk, as has been supposed by some authors, because the same quantity of pure water would in no wise produce the same results. It is evident, therefore, that only the sugar and salts possess the diuretic properties, their action being similar to that produced by salts of potash and soda by their osmotic power. These diuretic properties seem to be much more powerful when the milk has not been boiled. It should, therefore, be taken unboiled, and fresh from the cow if possible, or, at least lukewarm, as cold milk does not act in the same way. It seems as if boiling the milk destroyed these properties; nevertheless, it must never be forgotten that some patients can digest milk only when boiled, so that the rule is not without exception. Another curious point in the action of milk is that it is equally powerful in cases where the cardiac affection is not combined with dropsy. M. See has often observed that patients who either no longer suffered from dropsy, or never had suffered from it, were extremely benefited by a mixed milk diet. The action of the heart became much calmer and more regular and the palpitation disappeared altogether.

ALOE AS A DRESSING FOR WOUNDS.—Dr. Millet, a French army surgeon, recommends powdered aloes as a dressing for wounds, both as a means of favoring cicatrization and for closing them. It is said to relieve the severe pain of wounds almost immediately, and requires to be renewed only at long intervals.—*Boston Medical and Surgical Journal.*

The Week.

The principal item of interest in connection with mining matters during the past week has been the change of management of the Gould & Curry mine on the Comstock, by which Alvinza Hayward and W. S. Hohart assume control. Mr. Hayward also now controls the Hale & Norcross and Yellow Jacket. The proposition to stop pumping in the Savage mine is a somewhat surprising one. After pumping constantly for three years they have concluded it will cost too much to do it three or four months longer. Of course the water will rise in the Hale & Norcross to the 2000-foot level, and prevent all work below. They will stop pumping until a drift has been run to connect the Combination shaft and Savage incline in the 2300-foot level, after which the water will run into the shaft and be pumped to the Sutro tunnel. It has cost \$50,000 per month to work and drain the mine. The action is pretty rough on the Hale & Norcross people, who will have to build bulkheads to keep the water out, or else pay to keep the Savage pumps running.

PERSONAL.—We send a large number extra of this 24-page issue of the PRESS to persons engaged in the industries specially represented by our paper, with the hope that they will examine its pages and fairly consider its claims for patronage. Should any receive copies (duplicate or otherwise) for which they have no use, they will confer a favor by passing the same over to others likely to be interested in such a publication. Assistance in increasing the circulation of our paper will give us greater power for usefulness. We shall strive earnestly to make the MINING AND SCIENTIFIC PRESS worthy of the grand field it occupies.

Our Journalistic Efforts.

The present number of the MINING AND SCIENTIFIC PRESS is submitted to the critical and learned reader as worthy of his support. We flatter ourselves that a glance through the pages before him will convince him, if he is not a subscriber, he ought to be, and that it will be for his personal benefit to be a constant instead of a casual reader.

To our old and valued subscribers it is but an earnest of our endeavors to increase the value and interest of the PRESS and furnish to them such material for instruction and thought as will aid them in their walks of life.

As an exponent of the mining and mechanical industries of this coast, and of popular science, the MINING AND SCIENTIFIC PRESS has been laboring for many years. None of these branches run in groove as in years gone by; there is no direct path by which they are to be followed; no royal road to the acquirement of their details. The branches and ramifications of the arts and sciences are endless, and the details of each offshoot a study in itself. No man in active life can be expected to have time to acquire intricate technical knowledge of many kinds; but all intelligent ones want at least an idea of what their co-workers are doing and want every item of information in their own branch.

The mission of the PRESS is to gather, digest and condense the results of observation and work in the various branches it represents, presenting it in a form in which the reader may acquire the knowledge necessary to him with the least possible trouble. Such things of importance as come up are given in detail, while others of less practical utility are presented so that a clear understanding may be had of them without tedious study or undue loss of valuable time.

It is unnecessary to call attention to special articles, they speak for themselves. We have, of course, as usual, given prominence to such as will interest the miner and metallurgist. We expect the coming year to make many improvements in our journal. Our list of correspondents has materially enlarged, and now includes many names well known to the mining community as experienced miners and metallurgists. We keep close watch on all improvements likely to prove of practical utility to our patrons, whether originating at home or abroad, and our many years' experience admits of a discrimination in this respect which is useful to our readers.

The widespread interest in mining matters, which has extended to the shores of the Atlantic, argues a new era of prosperity to our coast, with which we shall keep pace. The prospects of the season are most encouraging, and the industrial classes of this coast have reason to congratulate themselves on their lot.

MINERAL SURVEYORS.—U. S. Surveyor-General Wagner is going after the U. S. deputy mineral surveyors about something which needed correction long before this. These deputies are many of them in the habit of making what are represented to be official surveys of mines, without instructions from the Surveyor-General's office, and returning such surveys to the courts or other officers instead of to the head office. He now apprises the deputies that U. S. deputy mineral surveyors have authority to perform in that capacity only such work as may be assigned them by the Surveyor-General's office—their appointments being in no sense roving commissions. When called upon by private parties to make surveys not ordered by the office, they should make them as private individuals, signing their names without reference to their positions as U. S. deputy surveyors.

SENATOR BOOTH has introduced a bill providing that where settlers enter upon lands supposed to be public, and subsequently fail to acquire titles, the fees and commissions they have paid in good faith shall be refunded to them.

The Comet mine of Montana has been sold.

The Prosperity of Mining Districts.

When the reputation of a mining district rests alone upon the fictitious value placed upon the stocks of that few of its mines which are listed in the Stock Boards, as is too frequently the case, that district must expect vicissitudes which will be far from pleasant. Those values are much too dependent on influences out of control of those most directly interested in the welfare of the mines themselves to be altogether agreeable. The desires or manipulations of a few operators exercise an influence which is unhealthy to the general prosperity of a group of mines. A disastrous termination to a stock scheme may be fatal to the prospects of a whole district.

This has happened scores of times, and, no doubt, will continue to happen so long as miners prefer to sell half developed mines to working them themselves on a small scale. Two or three dozen prosperous little mines in a district worked by their owners do much more for the neighborhood and the camp than one big one worked by a company of non-residents.

The manipulations of a set of sordid, unscrupulous operators in Idaho mines, a few years ago, set that Territory back many years in its mining development. So disastrous were the results and so shame-faced the schemes that California capital has hesitated ever since to invest in Idaho mines, and the people are afraid of them. Yet the mines are good—far better, indeed, than many in the market now. Similar instances might be cited with relation to a number of districts.

A camp to be prosperous, permanently so, must depend on its hullion product more than on the stock value of its prominent mines. The fact that a dozen mines of a district are quoted in the market is by no means a sure indication of good times. The fact, however, of weekly hullion shipments, is such an indication. It is to the mines themselves, therefore, that we must look for the basis of permanent prosperity; not for what they can be sold for, but for what they can and do produce.

Mining Superintendents.

The choice of superintendents in inaugurating any new mining enterprise is so very important a question, as involving more or less the prosperity of the mine, that it should never be settled without proper consideration; yet it is a question often settled at the first meeting of a new company, and without any very special examination into the capabilities or knowledge of the candidate.

That often used phrase, "gentlemanly superintendent," does not cover by any means all the requirements of the executive manager of a mine. Nevertheless, social qualities are as apt many times to influence a decision of this kind as sterling merit of rougher grain.

As a rule the mining men of this State and Nevada have had their eye-teeth cut in the matter of superintendents. In newer mining countries, mistakes which we have outgrown are still prevalent and people will have to learn by their own experience.

Ruinous failure is too often the result of a misguided choice of superintendent of a mine. There are plenty of competent men to fill the places, but unfortunately there are still more incompetent ones, and the latter are apt to be the more persistent in their applications. We have no doubt that among the many mining ventures now being organized in the East, dozens of failures, to be laid to the mines, will occur through the superintendents alone. It is safe to predict this. The directors will want to put in men of their own acquaintance, with more regard to their faith in a business capacity than their experience in mining matters. Yet it is possible to combine these qualities and in a high degree. There are hundreds of men on this coast with an experience of half a lifetime to back them.

Our own fear in this connection is more for the injury indirectly done to the mining industry than that to individual mining companies, which can only blame themselves. If to oblige some important man among them, the directors send his nephew, cousin or friend, simply because he is a nephew, cousin or friend, without questioning his ability and experience, they will reap as they sow, and should blame none but themselves.

It will be just as well therefore if our Eastern friends in engaging their managers, make no extended contracts as to the time of employment, in case they find they have made a mistake, and consider it necessary to replace them.

The United States Board of Trade adopted a resolution for a committee to award a prize of \$1,000, offered by a member, to the person who should draw up for passage by Congress the best Act looking toward the regulation of the sale of food and the prevention of adulterations thereof.

PARAFF, formerly of "Bull-Butter" fame in California, and later the man who ewindled the Chileans by making them believe he was getting lots of gold out of copper ore, has been granted a full pardon by the Chilean Government in consideration of important services at the artillery barracks.

Formation and History of the Comstock.

We received this week copies of the new book, entitled "The Comstock Lode, Its Formation and History," by John A. Church, E. M. Ph. D., the expected publication of which we have previously mentioned. The volume contains the results of studies which have been made from the standpoint of the miner rather than from that of the stratigraphical geologist, and the lessons derived from mining experience have received special emphasis.

The greater portion of the book was originally prepared as a report to the Chief of the United States Survey, and covers but one part of the great problem which the Comstock region offers to the mining engineer.

The following index to chapters will give the scope of the work better than an extended review: Chapter I, The Comstock mines; II, The Comstock lode; III, The lode rocks; IV, History of the lode rocks from the beginning to the formation of the quartz hodie; V, Formation of the ore quartz, and position of the bonanzas; VI, Description of the mine; VII, Position of the ore; VIII, Summary; IX, Considerations which affect the Comstock. These are the search for bonanzas, depth of lode, parallel quartz hodies, future yield, zonal arrangement, ore channels, the divide, the east clay, position of ore hodie, crushing, etc. Chapter X is devoted to general considerations, and XI and XII to the Justice lode, and to Heat Phenomena.

The work is fully illustrated with very clear and well-made colored engravings, showing ore bodies and details of underground work. It is handsomely printed on heavy tinted paper. There are so many points of interest in this book to be noticed, that it is scarcely worth while to particularize them, since every page will repay close perusal. The statistics given in connection with the yield, etc., are brought down to latest dates.

Dewey & Co., 202 Sansome street, publishers of this journal, have the sole agency here for the sale of this work, and a limited number of copies have been placed in their hands to dispose of at publisher's rates—\$8. per volume. An agent will shortly call upon some of our mining engineers and experts with a copy for their inspection.

In this connection, attention is called to the diagram on another page of this issue, showing a longitudinal section of the famous lode. It is engraved from a recent map, and the ore bodies are all marked, as well as the proper depths of shafts, inclines, etc.

A Decision in the Lick Estate Case.

It will be recollected that before James Lick, the millionaire, died, he made a deed of trust, giving his vast fortune to certain trustees, who were to distribute it according to the terms of the trust among a number of beneficiaries. A large sum went to the University of California for an astronomical observatory; money was donated to establish public baths in the city, an Old Woman's home, etc., etc. The residue of the estate was to be divided equally between the California Academy of Sciences and the California Pioneers.

Although Mr. Lick's son, John Lick, was one of the trustees, he refused, after a time, to act as such. He and the other heirs were disposed to contest the deed of trust, but a compromise was effected by which he was to receive \$383,000, and release the estate from further claims. It was determined to take this compromise money from the residue belonging to the Academy and Pioneers, and an amicable suit was brought to ratify the compromise.

The Academy of Sciences objected to paying from their share half the compromise money, arguing that since all would be benefited, all the beneficiaries should contribute pro rata. The question was submitted to the courts, and Judge Wheeler decided a pro rata arrangement was impossible, and that the residuary legatees should pay the compromise money.

The Academy of Sciences appealed the question to the Supreme Court, which on Wednesday affirmed the previous decision. The compromise money must therefore be paid from the residuary shares of the Academy of Sciences and Pioneers. It is hoped this will lead to the immediate distribution of the property by the trustees, which has been too long delayed. It is hardly probable that anything will be realized from the estate by either the Pioneers or the Academy, outside of the lots on Market and Fourth streets which they hold under separate deeds, for the simple reason that the estate is not large enough.

However, both of these societies can sell their property if they choose, although they will be unable to carry out the idea of the donor, which was to erect magnificent buildings upon the lots, for which purpose the residuary amounts were to be utilized. Neither society will now be able to do this unless more than is expected is realized from the sale of the property of the estate.

We have on hand a description of the Hoffman leaching process, written by Guido Kuetel, which we are obliged for want of space to lay over until next week. It describes a method of working auriferous silver ores.

DOUBLE SHEET—24 PAGES.

Preliminary Reports on Mines.

We have been favored by M. P. Aasoa, examiner of mines, No. 6. California street, in this city, with the following useful memoranda, which we are sure will be appreciated by the mining community. The form of report will be very handy for reference:

The subdivided form for synoptical reports on mining properties, briefly filled out for exemplification, is intended to supply a want which many have doubtless felt in common with the writer.

In correspondence with miners concerning their mines and prospects, I have often found it difficult to obtain the information desired in a succinct and comprehensive form readily available for reference. The statements received are too generally diffuse and indefinite, often omitting the points most essential in determining whether or not a mining property is worth further consideration and the trouble of a proper inspection.

It is no new thing to say that my fellow-miners are a sanguine class, lavish of hyperbole and prone to accept and announce a phantom hope for fact; but I am aware that in many instances their exaggerations and ambiguities are intentional substitutes for exact statements of fact which, if given, would bar the hope of sale or examination of their properties.

To such, the following arrangement will prove an unwelcome catechism; but to those who desire to attract the attention of investors to really meritorious mines, it will doubtless be helpful in condensing and systematizing their statements.

I find that a blank of this character, sent to be filled out as fully as possible, while eliciting all needed data for the immediate purpose, confines the informant to definite limits; saves time and simplifies his work and mine.

With slight modifications, this form may be used for descriptions of placer mines; and when printed in a note book, with such changes or additions as individual experience may suggest, will also be of service in the field, to mining engineers, experts and others, as a concise and methodical record, besides keeping in view the scope and essence of enquiry.

Form for Report.

Name of mine.....	Blank mine.
Mining district.....	Hassayampa district.
Locality, etc.....	Yavapai Co., Arizona.
Date of location.....	April 1st, 1878.
Where recorded.....	Recorded at Prescott.
Names of locators.....	John Smith and others.
Names of present owners.....	John Smith and others.
Present title.....	Discovery claim (not patented).
Dimensions of claim.....	Six hundred by fifteen hundred feet.
Description of mine.....	A gold and silver-bearing vein.
Character of gangue.....	Quartz.
Average width of vein.....	Thirty-six inches.
Strike of vein.....	Northeast.
Dip of vein.....	About 60°.
Extent of outcrop.....	Lineally 4,000 feet; occasionally bold.
Character of footwall.....	Gneiss.
Character of hanging wall.....	Clay-slate.
Hardness of walls.....	Easily worked—no blasting yet.
Gouge or selvage.....	Clay seam of variable thickness.
Assays of the ore.....	Lowest, \$54; highest, \$932.
Gold, per cent.....	23% gold.
Silver, per cent.....	77% silver.
Base metals contained.....	Pyrites, galena, traces of copper.
Character of ore.....	Chloride 30 feet down; sulphide below.
How chiefly occurring.....	Well distributed through the vein.
Amount of ore in sight.....	Not estimated.
Ore extracted, not worked.....	About 70 tons.
Estimated value.....	\$100 per ton.
Ore worked.....	Twenty tons.
Method of reduction.....	Roasted, dry-crushed and panned.
Average yield per ton.....	\$103 per ton.
Cost of extraction.....	\$3.50 per ton.
Cost of reduction.....	\$20 per ton.
Reduction works, etc.....	None belonging to the mine.
Drainage requirements.....	Eight-inch pump needed at present depth.
Drainage facilities.....	Drainage by adit not practicable.
Development work done.....	A shaft, 5x5 feet, down 55 feet; drift from bottom 32 feet to the lode.
The water supply.....	Fifty inches free water seven months.
The timber supply.....	Forests of pine and oak adjacent.
Wood, per cord.....	Delivered at \$3 per cord.
Nearest wagon road.....	A road to the mine.
Nearest important town.....	Prescott.
Topography.....	Mountains, deep canyons, etc.
Climate, altitude, etc.....	Temperate; elevation, 6,000 feet.
Other information.....	
Price asked (cash).....	
Time and terms of bond.....	
Other conditions, etc.....	
Remarks.....	

QUICKSILVER.—For two years past parties have been engaged in tunneling a bill on the ranch of A. S. Howard on Marsh creek, in search of cinnabar. The Antioch News says the tunnel is in about 150 feet, and it is authoritatively reported that a vein two feet in thickness and well defined has been discovered during the past few days. Richard Matthews is the name of the gentleman who has made the discovery and he thinks he has an excellent prospect. The croppings, extending for miles from the Marsh ranch toward the Mount Diablo foothills, indicate a quicksilver vein. Parties have prospected at times for several years, but this is the first discovery that promises good results.

Chemical Engines.

We show herewith engravings of two forms of the Connelly fire extinguisher, for which Messrs. Parke & Lacy, of Nos. 21 and 23 Fremont street, are now agents for this coast. The Connelly & Martin extinguishers are now in use in many mills, factories, depots, public buildings, hotels, theaters, steamships and steamboats. They are made in sizes varying from 100 to 600 gallons in capacity; are simple in construction, easily operated, and in case of fire can be brought into use in less than 10 seconds.

In buildings, factories, etc., the apparatus is

Amalgamating Plates.

Within the past few years the practice of using silver-plated copper plates for amalgamating purposes in mills has become quite common, and all of our best mills are now supplied with them, mainly from the San Francisco Plating Works, where a specialty is made of this kind of work. The method by which the plating is done there is simple, but it is hardly practicable without special appliances. Miners in isolated camps or in places where time is lost in sending so far, or those persons who wish to test the efficacy of the silver-amalgam coating, can pre-

pared to receive this by being thoroughly cleaned with a solution of nitric acid, and when the amalgam is spread over the copper a fine silvered surface is presented. Take a fine broom and draw across the plate and little fine ridges of silver amalgam are formed, the plate being thus beneficially roughened.

The plates thus prepared will be found to act a great deal better than plain copper plates simply coated with mercury, and the silver can of course be obtained whenever the plates are done with. The coating will not of course last as long as if it were electroplated on the copper, but the operation can always be repeated at any time. Care must be taken in handling the acid, or the hands will be burned.

For quicksilvering plated plates, quicksilver should be rubbed on with a piece of flannel, using water—no acids or cyanide of potassium. In quartz mills the silvered plates should not have a fall of over three or four inches to 12 feet, as silvered plates should have less fall than plain copper plates. If they do not keep free, more water should be used to carry off the sands. To remove the amalgam a piece of leather or rubber belting should be used, but a metal scraper is objectionable.

A silver-plated surface will hold more quicksilver, and will not turn green or corrode like the copper plate. It is always therefore in condition to save the amalgam or amalgamate the gold. The quicksilver is absorbed as soon as applied.

Railroad Building.

We seem to be entering on an era of railroad building similar to that which prevailed a few years ago. New roads are being projected in all quarters. Several lines are being projected to Omaha and the West, the city just mentioned being an important terminal point. Oregon and Washington are about to develop the immense resources of their great and important territories by means of new lines of road, and soon the West will be as well seamed with them as the East. Two hundred miles will be constructed next year, which will bring millions of acres, with all their magnificent resources, within reach of shipping points. Fifteen hundred tons of rails are now on board the ship Orient, bound from Cardiff to Portland. The line will extend from the Dalles to the Walla Walla railroad, thence to Snake River and to the heart of what is known as the Palouse country. This will connect with the North Pacific, in which rapid progress is making.

The lines from the West to California will probably be pushed partly through next year. The Southern Pacific branches will be rapidly approaching the Rio Grande on the one hand and the Mexican border on the other. A line from Utah will be threading its way towards San Diego.

An important question is how far all this will inure to the benefit of San Francisco. With the exception of the Oregon and Washington roads, as far as we are now advised, very little. If the overland lines all center on the Southern Pacific, it will rather be to its detriment, for the policy of that line is opposed to the interests of our city. Already the trade of Arizona is slipping away in consequence of the discriminations made in favor of Eastern shippers. Nor is this all. Some time since a Los Angeles merchant commenced shipping potatoes to Arizona, and sent four carloads thither at \$100 per car. On learning that they had been sold to advantage, the agent raised the price per car to \$400, or 2 cents per pound. Now, when it is remembered that potatoes, after having been shipped from the country to San Francisco, have sold as low as 20 cents per sack, or one-fifth of a cent per pound, the effect of a freight that charged ten times the first cost at one time, or four times that cost now, may be estimated. Now, the trade of Arizona in this one item might be developed to great extent, as at the rate of only 1/2-pound per day to each person, a consumption of a couple of hundred cars in a year would be the result. No line will be of the least use to San Francisco which does not terminate in this city or at some seaport where a cheap steamer line can be laid on. Then we will have a chance, through cheap competing freights, to take our share of the trade of the Mississippi Valley in grocery goods, in teas, sugars and coffee, which reach an imported value annually of one hundred and forty millions of dollars.

Short lines of roads from the Sacramento and San Joaquin rivers into the mountains would be of inestimable benefit to the State, in bringing all its farming lands within reach of cheap water transportation to this city. San Francisco must have a railroad policy for herself.

SALE OF MINING GROUND.—The tract of gravel ground adjoining the Planet Company's claim, between Steep Hollow and Bear River, has been purchased by M. Byrne, Jr., of Grass Valley, from its former owner, F. McGuire. From the developments made on either side of the ground, it has been demonstrated that an extensive gravel channel must run through it.—Grass Valley Union.

CONNELLY & MARTIN SYSTEM OF FIRE EXTINGUISHING.

located on the ground floor or in the cellar, with stand pipe running to the top story, having connections and hose on each floor, so that it can instantly be brought into use in any part of the building.

This system is especially adapted for use on steamships and ocean vessels. The dry gas apparatus is so constructed that carbonic acid gas can be instantly discharged into the hold of a ship while at sea, and in a moment extinguish a fire of any dimensions, it being under perfect control of the engineer.

The stationary apparatus charged with water impregnated with carbonic acid gas can be brought to play instantly upon a fire in the cabin or outside of the vessel, extinguishing the fire without damage from the liquid.

One of our engravings show the system applied in a building. The other engraving is the Connelly warehouse extinguisher, designed for warehouses, hotels, farm houses, mills, etc. It has a capacity of 40 gallons, and being mounted on substantial wheels two feet in diameter, can be easily transported and operated by one man. It being always under pressure there is no necessity for agitation when its services are needed; and being provided with two valves, the operator, on opening the one at the apparatus, is free to operate the nozzle, so no time is lost in bringing it into use. It contains no acid and the discharge has no injurious effect upon goods or furniture. This is specially useful about quartz mills, boiling works, etc., being readily moved by one person to where it is needed.

pare the plates themselves in a simple manner and without the use of electricity.

To do this, take 10 or 12 half-dollar pieces (greenbacks even at par won't answer) and drop them into a glass or porcelain vessel containing nitric acid. The action of the acid will give them a solution containing nitrate of silver and nitrate of copper. This solution should be diluted with water free from saline material. Into this solution enough quicksilver may be poured to form a pasty mass with the silver,

CONNELLY PORTABLE EXTINGUISHER

with which it amalgamates to form a silver amalgam.

The nitrate of silver is decomposed by the presence of the metallic mercury. A portion of the nitric acid will form nitrate of mercury, which will be lost, and the metallic silver set free from the silver amalgam. The solution poured off will then contain nitrate of copper and some nitrate of mercury.

Take the residue and strain off the excess of mercury through a buckskin bag, and there will remain a solid mass of absolutely pure silver amalgam. The copper plates should be pre-

The Metric System.

The metric system of measurement, which a few years ago was confined to a single country, is rapidly spreading in use, and the people of all nations are more or less familiar with it. All scientific documents, papers, proceedings, etc., cite items of measurement under this system, and in all the learned professions it is necessary to understand the system thoroughly. It is much better adapted to the ordinary business of life than the varying table of measurement now in use, if people would but take the trouble to give it thought enough to understand it.

"Measure all lengths in meters, all capacities in liters, all weights in grams, using decimal fractions only, and saying deci for tenth, centi for hundredth, milli for thousandth, deca for ten, hecto for hundred, kilo for thousand, and myria for ten thousand."

This sentence comprises the entire system, for surfaces and bulks are simply the squares and cubes of the measure of length, and the "ar" and "ster" are only other names for the square decimeter of land, and the cubic meter of firewood.

The meter (measure) is one-tenth millionth of the distance from the equator to the pole, and equals the distance from the tip of the fingers to the center of the opposite breast. Four steps equal three meters. The width of the hand is a decimeter; and of the fingers, two centimeters. The liter (capacity) is simply the cube of a decimeter (tenth measure) in the more convenient cylindrical form; and the gram (weight) is simply the weight of a cubic centimeter (hundredth measure) of water.

single sentence above takes the place of compound or denominate numbers in our arithmetics; and as a result large committees of our ablest teachers report that a full year may be saved in the school-life of every child. The gain in commerce is much larger, for a single multiplication or division gives an absolutely accurate result, where the common system requires several operations to get often only an approximate answer.

Hectometer,	Hm.	"	"	100	m
Kilometer,	Km.	"	"	1,000	m
Myriameter,	Mm.	"	"	10,000	m

The meter, or unit of length equals... 39.37 inches.

... 3.28 feet.
... 1.09 yards.
... .19 rods.
... .0006 miles.

Measures of Surface.

Centar ca.	equals	...	.1	sq. m
Are A.	"	"	100	sq. m
Hectar Ha.	"	"	10,000	sq. m

The are, or unit of surface, is a square the side of which is ten meters and surface 100 square meters. In U. S. surface measure, it equals

155,006.	square inches.
1,076.	square feet.
114.	square yards.
3.	square rods.
.098	square rod.
.024	square acre.
.00003	square mile.

Measures of Capacity.

The liter, or unit of capacity, is a vessel whose volume is equal to a cube whose edge is one-tenth of a meter and capacity one one-thousandth of a cubic meter.

Millimeter,	ml.	equals	...	.001	l	= 1 cu. cm.
Centiliter,	cl.	"	"	.01	l	
Deciliter,	dl.	"	"	.1	l	
Liter,	l.	"	"	1	l	= 1 cu. dm.
Decaliter,	Da.	"	"	10	l	
Hectoliter,	Hl.	"	"	100	l	
Kiloliter (or Ster) Kl.	st.	equals	...	1,000	l	= 1 cu. m.

The liter equals	...	.61.027	cubic inches.
...	...	.035	" feet
...	...	8.453	U. S. gills.
...	...	2.113	" pints.
...	...	1.056	" quarts.
...	...	.264	" gallons.
...	...	1.763	Imperial gills.
...	...	.880	" quarts.
...	...	.220	" gallons.
...	...	.110	" pecks.
...	...	.027	" bushels.

Weights.

Milligramme	mg.	equals	...	.001	g
Centigramme	cg.	"	"	.01	g
Decigramme	dg.	"	"	.1	g
Gramme	G.	"	"	1	g
Decagramme	Dg.	"	"	10	g
Hectogramme	Hg.	"	"	100	g
Kilogram (Kilo.) K.	"	"	"	1,000	g
Myriagramme	Mg.	"	"	10,000	g
Quintal	Q.	"	"	100,000	g
Ton	T.	"	"	1,000,000	g

The Gramme equals... 15.434 grains.

... .032 ounces troy.
... .0352 ounces avdps.
... .026 pound troy.
... .0022 pound avdps.

Gramme equals weight of... cu. cm. of water Kilo. " " cu. dm. of water Ton. " " cu. m. of water

We append the following tables, which give, in a condensed form, a comparison of other measures with the metric system, and by means of which anyone can institute comparisons readily. They must not be understood as tables of the system, for as before stated, there are no tables or scales at all. It will be seen that the single prefixes do away with all this necessity of having a separate set of tables for each class of measures and a separate name for each subdivision of each class.

Long Measure.

The metric system, by which so much is accomplished, has now been adopted by 28 different nations, including a majority of the civilized world. In 11 countries it is in exclusive use; and in several, like Germany and France, there are penalties for using any other measures.

The educational society incorporated to secure this result desires the co-operation of every friend of economy and education, and will gladly send full information to applicants who address the American Metric Bureau, Boston.

NATIVE BRITISH SILVER AND GOLD.—The quantity of silver obtained in 1878 from British mines was 397,471 ounces, and most of the precious metal was found in combination with lead. The total value of the silver thus obtained in the year in question was estimated at £38,296 19s. 6d. In the same year the gold found in British mines weighed 702 ozs. 16 dwts. 3 grs., and was estimated to be of the value of £2,848 15s. 2d. Nearly the whole of this British gold—a fraction over 697 ozs.—was procured in Wales, in the Clogau mine in Merionethshire. The balance of 5 ozs. and a fraction was found near Wicklow, in Ireland, in 86½ lbs. of ore. Of silver ore, about 94½ tons were found in Cornwall in the Huel, Prince of Wales, and Redmoor mines, which yielded silver to the value of £5,994 11s. 10d. The richest argentiferous lead ores are found in the Isle of Man, where the 3,920 tons of lead ore procured from the nine Manx mines yielded in 1878 as much as 110,496 ozs. of pure silver. In Wales, which possessed 97 lead mines in 11 counties, the silver won in 1878 weighed 148,376 ozs. England, with 266 lead mines in 10 counties, produced 118,629 ozs. of pure silver in the same year, while 14,320 ozs. were got from the lead ores produced in Scotland, and 5,650 ozs. from those of Ireland. The quantity of British silver produced in the year was rather more than 11 tons,

A New Form of Roasting Furnace.

A new furnace has just been completed at the Union Iron Works, for the Columbia mine, near Tuscarora, Nevada, which is of peculiar construction and operation. It was invented by Miles B. Dodge, the patentee of the Dodge crusher. It is a rotary furnace, but instead of being cylindrical has angulated sides, being hexagonal in form. Each of the sides is slightly rounded, but only sufficiently so to form arch enough to hold the brick lining in place properly.

A dust chamber is formed at the outer end of the furnace connecting with the stack, and on top of this chamber is a hopper connecting with a curved pipe leading through to the furnace. When the furnace is to be used for continuous work on light ores the ore is fed through this hopper and pipe.

At the opposite end is a discharge chamber, and separated from it by a fire-wall is the fire-place which supplies the necessary heat. The discharge opening of the furnace is larger than the feed opening, in order that the ore in the furnace, when being fed continuously, may be discharged automatically without the necessity of any conveyers, inclined flanges or other interior obstructions to the free action of the ore.

On the sides of the furnace are the charging and discharging doors, which are used when it is run by charges. In continuously operating the ore travels in an opposite direction to the flame and heat.

The rotation of the furnace keeps the ore level, and by having the entering opening smaller than the discharge opening the ore will continually discharge, since the constant addition of ore keeps the mass enough above the edge of the larger opening to admit of the ore continually passing out of the discharges end. As the rotation keeps the ore level at all times, it must necessarily pass out of the larger opening. The furnace can, therefore, be made without having to be set on an incline, and without conveyors or screw flanges to pass the ore through.

Those furnaces having ribs, carriers, conveyors or other flanges which raise the ore up and shower it down through the flame, are open to the objection that the draft carries off quantities of ore in dust, only a certain proportion of which is lodged in the dust chambers. Trouble is involved also in repeated cleanings of the dust chambers. Smooth cylindrical revolving furnaces, with no projections, such as are made to obviate the difficulty above mentioned, are objectionable in another sense. The ore is apt to stick together by sliding in mass as the cylinder is revolved, and is not sufficiently agitated or stirred up, and none of the particles have time enough at any one period to become thoroughly oxidized or desulphurized. To accomplish the object, therefore, the ore must be kept in this furnace during a lengthened period.

It is to overcome these objections that Mr. Dodge makes his new furnace many-sided, instead of cylindrical. As the furnace revolves, the ore resting on the rising side remains stationary, being held there by the corner formed by the junction of the sides. At a certain point, however, the whole mass on that side drops down and is completely turned over and stirred up in so doing. This outer surface of this body then remains in contact with the heat and flame during the time the side which is carrying it is raised up as the furnace rotates, when another sudden fall of ore takes place and the operation is repeated.

It will be noticed that this turning over of the ore will take place below or at one side of the line of draft. The line of greatest draft is between the centers of the feed and discharge openings, and when ore is showered down as in other furnaces across this draft, loss ensues by the dust being carried off.

For ore requiring a very long roasting for desulphurization, this furnace is worked by charges, as is intended to be done by the furnace which has just been built at the Union Iron Works. The ore is then charged into one of the side doors instead of through the hopper, and after being thoroughly roasted, is discharged through the same or a corresponding door. In this furnace, in which the ore is to be worked in charges, the brick lining is so put in that the ore circulates from end to end without showering. It therefore chloridizes very evenly.

The furnace is revolved by peculiar gearing. The bands encircling the furnace rest on oppositely placed pairs of grooved rollers. The shafts of one pair of these rollers are extended past the bearings, and on their ends are pinions, between which is placed a gear wheel. On the opposite end of the shaft carrying this gear is a crown wheel, and this being revolved, the center gear rotates the pinions both in the same direction, thus moving the rollers in the same direction and rotating the cylinder, applying the power on both sides.

It is sometimes necessary to run faster than at others. When continuously working, a slow speed is maintained, but when charge it may be rotated more rapidly when it is desired to throw the charge out quickly. The gearing is so arranged to alter the speed at will without altering the speed of the driving engine. The furnace to which we refer is the largest one of this class of revolving furnaces we have seen, and is designed to work seven tons of ore at a charge. It is 7 feet in diameter and 16 feet long.

Definition of the Various Measures of Metric System.

Meaning.	Spelling.	Pronunciation.	Illustration.	Abbreviation.
length	meter	meeter	like a meter	m.
capacity	liter	leeter	as in liter	l.
weight	gram	gram	like gram	g.
hundredth	centi	centi	like cent	c.
thousandth	milli	milli	like milli	m.
ten thousand	myria	myria	like myria	M.
surface	are	are	area	a.
solidity	ster	ster	stereoscope	st.

The names meter, liter and gram, are from Greek words, understood in all modern languages to mean a measure (as a gas-meter, water-meter, etc.) a capacity and a weight. As the metric system is now used by most nations and will soon be universal, the names understood by all nations are used, instead of measure, capacity and weight, which would be understood only by the English. For the same reason the fractions are not called tenth, hundredth and thousandth in English, but by their Latin names, deci, centi and milli. The large quantities, instead of ten, hundred and thousand, are called deca, hecto, and kilo the Greek words for these numbers. These words are short, avoid all danger of confusion, are understood by all nations throughout the world, and so are very much to be preferred. We therefore say, not hundredth measure, but centimeter. Not one thousand grams, but kilogram, etc.

Each prefix is an independent word, accented on the first syllable, and retains this accent in the compound, centimeter, not centimeter, etc. The abbreviation for the compound is simply the letters for the two parts, dm. for decimeter, Dm. (with capital) for decameter. For shorter names of the compounds, pronounce only the prefix and the first letter of the unit, saying centim, millim, decil, hectog, etc. The system will be understood best by remembering that our system is really a part of the metric system. The dollar is value, as the meter is length, the liter is capacity, and as the gram is weight. A decadollar we call an eagle, a decidollar a dime, and the centidollar and millidollar are shortened to cent and mill. Both the money and metric system correspond perfectly to our arithmetic.

The following will show still more clearly the application of the prefixes, and being in a convenient form for reference, is worthy of preservation:

Deci.	expresses the	...	10th part.
Centi.	"	...	100th part.
Milli.	"	...	1,000th part.
Deca.	"	...	10 times the value.
Hecto.	"	...	100 times the value.
Kilo.	"	...	1,000 times the value.
Myria.	"	...	10,000 times the value.

There are no tables, or scales, or complicated relations. With the meter, every possible dimension (length, surface or solidity) can be measured; with the liter, every possible capacity; with the gram, every possible weight. The

Is the Comstock Dead; or Where do Mineral Deposits End?

Radical Changes Demanded—Suggestions and Results.

(Written for the Press.)

As one who knew the Comstock in its beginning, and received his first impressions of its value from surface indications—there being no opening on the whole line over 25 feet in depth when I first examined it—naturally its progress by development, its ups and downs, have ever received from me a due amount of watchfulness, interest and calculation. With all mines there are periods of change for profit and loss, consequent upon rich or poor deposits of metal. The Comstock has had depressing periods before the present one, but at this time there seems a crisis, and in the minds of many the question arises: Is the Comstock for profit virtually dead? I will ask, if other mines have for a time universal barrenness, why should not the Comstock? If mines pay above, why should they not pay below? If they have rich deposits at 2,000 feet depth, I want any mining agent to give me a scientific or practical reason why they should not have at 5,000 feet depth, the formation remaining the same below as above. I admit a change of formation may produce a change in the mineral deposit for better or worse. Now, when we stop to think, what is 5,000 feet for depth upon the crust of the earth, which in its thinnest part is estimated to be at least 20 miles in thickness, and from that to 200 miles? Thus we can see how insignificant is the "enormous" depth of 2,500 feet. The writer at one period, and after investing for himself and others over a quarter-million of dollars, saw on the Comstock what was considered by many the bottom of the lode. There was, at this time, considerable of a scare, especially among the owners of the Gold Hill section. A consultation was had by a goodly number of owners, and with their big scare on, several called to see what your humble servant thought of the situation. I had already studied the position of affairs and my mind was fully matured. When the question was asked, "What is the best to do?" my answer was, "Go down, or go up," and so I now say, "Go down or go up." There is no other alternative; the life or death, practically speaking, of the Comstock, is in the question of depth, and in this development there is the same speculation as to the value of undeveloped mineral deposits as there was above. To accept the ideas of the justly celebrated Dr. C. T. Jackson, of Boston, whom I had the pleasure of accompanying, in his examination of the Ophir many years ago, and who, in speaking of the lode giving out, remarked: "How can there be so much above and nothing below? It is hardly probable that the lode was formed above and had to grow down. It was formed below, and came up!" This doctrine is as good for 5,000 feet as for 2,000, so that going down is simply a question of temperature, ore and pay. Science and mechanics can overcome the rest. The Doctor was a believer—at that time at least—in the igneous theory for the formation of lodes; but whether this theory is correct or not, I will not argue at this time.

Because the silver mines of Mexico, or other parts of the world, have not been worked below 2,500 or 2,800 feet, is that any sign that metal is not to be obtained below these levels? Had Mexico, when these deep mines were abandoned, the great mining appliances of to-day, they would have continued as will the Comstock; in fact, many of these mines are now being reopened. The great wonder is they went so deep with the crude way they had of mining.

So much for the question of depth and possibilities of ore deposits. The matter of handling and reducing the ore from these greater depths is the next question for consideration; and right here I wish to say that I am not writing this in the interest of any individual or company; I am simply giving my views; they may be right, and they may be wrong; others must judge. These views may be hurtful to some and beneficial to others, so they may think; I know not of that. Now, considering the present, 1st, excessive depth; 2d, the high temperature of the lower levels; 3d, the grade of ore; 4th, the excessive expenses of running the mines. These all considered make the present a critical period for the Comstock, and it seems to me that it is a time when extraordinary changes should not only be talked of, but should be at once entered upon, as, when made, then would the cloud lift that now overhangs all the companies engaged thereon. Now comes the question, what do I call extraordinary changes. I wish to say again we are considering profitable mining, not interest of mills or mill-owners on the line; simply profit and loss of mining, and to that end I would say, 1st. Let all the companies accept the Sutro tunnel as the salvation of the Comstock, and from one end of the line to the other extend to it their capital, enterprise and influence. 2d. On the line from Utah to Overman, I would form two companies; (1), the North Comstock, which would embrace the Savage, Gould & Curry, Best & Belcher, Con. Virginia, California, Ophir, Mexican, Union Con. and Sierra Nevada, embracing a line north of where the tunnel intersects the lode of 8,593 feet; (2), the South Comstock, which would embrace Hale & Norcross, Potosi, Chollar, Bullion, Exchequer, Alpha, Con. Imperial, Challenge, Confidence, Yellow

Jacket, Kentuck, Crown Point, Belcher, Seg. Belcher and Overman, all aggregating in length 8,130 feet, about the same as the north section. Just imagine what would be the saving in the matter of management alone, when we consider the expense attending each of these companies as enumerated, of which there are nine on the north and fifteen on the south. This item alone is worth compiling. This consolidation agreed upon, and the lateral tunnels of Sutro completed of a size as now set (8x8), or larger, and capable of a double-track, narrow-gauge railroad, the next move should be to introduce water power on the level of Sutro tunnel, and for operating both above and below, and thus do away with another enormous expense. Some may say there is not water enough to be had for power. Lake Tahoe can supply enough, and what would it be for such companies to bring in the required quantity? This water could be conducted down the various shafts, giving a pressure from 1,600 to 1,900 feet. Let us see what power this would give by the use of the Knight pressure wheel:

50 lbs of water, 1,000 ft pressure, will give 100 horse power	330
100 " " " " " "	700
50 " " " " " "	193
100 " " " " " "	454
200 " " " " " "	831

It will thus be seen that a great work a comparatively small amount of inexpensive water is capable of performing, and does it not seem as though the great saving in this direction would engage immediate attention?

In this connection I will add that all the water of the mines, from surface to within 100 feet or so of the Sutro tunnel, can be utilized and made to play an important part in the economical handling of waste or ore.

Besides the enormous saving, as between steam above and water power below, the water would operate in cooling the atmosphere of the lower levels and tunnel, as it moved on and out to do another great service, as a cheap power, for reducing the ore. In the matter of water for power, it may be argued that at stated distances you would have to sink shafts to introduce water. I will answer this by saying, there are shafts enough already, and if not, power could be transmitted the whole or any part of the line. There is nothing in this but what can be mastered in this mechanical age.

These suggestions I do not claim to be wholly new; they will at all times suggest themselves to the practical miner; but they may be impracticable to carry out on account of opposition from those not directly interested in paying assessments. Who, thus directly interested, will say that the programme is not correct? This plan would form three great companies—first, the Sutro Tunnel Transporting Company; second, the North Comstock Consolidated Company; third, the South Comstock Consolidated Company. And who would not prefer to invest in Comstock shares under such an organization? Would not the mining world have more confidence in its future than it has had in the past. The fact is, this programme in full operation, the era of profitable mining on the Comstock will have only begun. And here I venture to say (ore bodies below being the same as above) that ore could be extracted and put into bullion at one-half it has cost from the beginning to the present time, so that profitable mining, as regards present depths, is no question at all, provided the Comstock companies at once start in for the adjustment of conditions, or to do that which they know is simply a common sense business proposition. Some may say this programme would be too extended an operation. Would its management equal that required by our railroad enterprises? It only wants consummation, and we need go no farther than the Comstock to find men of business calculation, order and capacity to grasp and to successfully work up so extended, if you please, an enterprise.

And here let me say, there is no time more propitious than the present to inaugurate the scheme. How it could be done, I have my views, which are not important at this time to present. Of the past or even present management of the Comstock, as all companies have been and are now necessitated to work, there is more or less unjust complaint. You cannot run enormous machinery and work at great depths on air. It takes money, and if money does not come out of the mine, it must come out of the shareholders' pockets. When it comes to the management of Mackey and Fair, to my mind, no two could, or would have done better. They have shown a dash, a daring, a capacity and a fidelity unequalled in mining anywhere, and if they have stored up great wealth, they have got no more than their enterprise, boldness and industry entitles them to.

Now comes the question, How would such a change as I here present affect Virginia and Gold Hill? I argue that what they would lose one way they gain in another. If some extended radical change at economical working is not made, the Comstock will have only a lingering existence until it drops out of favor entirely, and with it goes both of these prominent localities. With a thorough system as here proposed for cheaply working the mines, the future twenty years looms up greater than the past, and with it is stability and prosperity for both places. What they may lose in milling ores they will gain in the greater underground population, who would always come to the surface rather than travel three to ten times the distance to daylight through the Sutro tunnel.

The great question in the minds of share-

holders now is, what will be done to relieve them of continued heavy assessment which they have got tired of, and which, unless some great radical change is made, they will stop paying, considering future profit under the present system hopeless. That this radical change should be made common business sense demands. The interest of stockholders, large and small alike, demand it. The great mining interest of the State of Nevada—yes, of the whole Pacific coast—trade, commerce and manufactures demand it, as profit to the Comstock holders is profit and good cheer for all. Will it be done?

ALMARIN B. PAUL.

December, 1879.

Rainfall Table.

The following very useful table of rainfall at Sacramento has generally been taken as representative for the whole State, since at no other

Arranged according to the seasons, showing the amount in inches of each month, during thirty years, and for each rainy season, to December 14th, 1879; also the quantity for every and the annual amount of rain.

Immigration to California.

There is no doubt that California is one of the best countries under the sun for the immigrant. Its genial climate recommends it equally to the native of the tropics as to him of the temperate zones. The former can find in the southern part of the State a habitat suited to him—the latter can live with comfort, so far as temperature is concerned, over the greater part of the whole State. The soil is equally suitable to the products of the tropics or the temperate zones. The vine, the fig, the olive, cereals of all kinds, silk, sugar, rice and cotton can be grown in one portion or other of its wide domains—some of the staples in all of it. Access by rail and steamer can be had to nearly all the desirable portions of the State. Its riches in gold, silver and other minerals are well known. The latter it was which originally drew the stream of Caucasian immigration to this coast; otherwise we are too far out of the beaten track to receive the immigration that we should and ought. The Mississippi Valley will not be fully settled for half a century to come, and the people of the Eastern States wish to take up the unoccupied lands of Kansas, Nebraska, Minnesota, Wisconsin and other States, inasmuch as they are nearer and as their friends and neighbors have preceded them to those sections. European immigrants come to New York, Philadelphia, etc., as more easily accessible, and those of them who want to go west seek the prairie and trans-Mississippi States, so that our great national attractions are in this manner offset. Now, immigration is the life-blood of a new country. So conscious were the men who organized the revolution of the last century of this, that one of their complaints against King George was that he had placed obstacles in the way of the naturalization of foreigners. Since that clause was written the cause of independence triumphed, and the results of a century of immigration and naturalizations of these foreigners are before us. And what are they? Ten millions of men and women, in the prime of health, life and enterprise, added to the population; a vigorous offspring of twice the number—forty-five millions of people from four millions, and a country devastated and impoverished by war to one with a wealth of forty-five thousand millions of dollars. California has the largest area of any State outside of Texas and is larger than either Great Britain and Ireland, or Italy, both of which have populations in the neighborhood of thirty millions, while we boast of only one.

We have room for millions yet. It is desirable that we should have them. But our people have been singularly apathetic in the matter. They should wake from that apathy. A few land associations from time to time have done a little in the matter of advertising the resources of the State and the value of the lands that they have had to sell. So far as good, though in matters of this kind the unfortunate immigrant is a liable sometimes to be taken in as was Martin Chuzzlewit when a land speculator sent him and his friend to find an Eden among the fever and ague breeding swamps of the Mississippi, and where the only variation of life's ennui was from burning to shivering and vice versa. We have, however, no such fever breeding lands in California, but it is as well to beware of the land speculator all the same.

The other evening a meeting of very respectable gentlemen was held in the parlors of the Baldwin, to do something to encourage immigration. An organization was perfectly effected, out of which it is to be hoped something practical in this direction may be accomplished.

It is advisable that agencies should be established in all the leading cities of Europe and America, giving information as to location of lands, etc., and how to reach them; such information as could not be otherwise obtained, and as would suffice to turn the tide California-ward. A bonus should be given to those vessels that would introduce the greatest number of immigrants. Lines might be laid on from Europe and the East by which immigrants could reach these shores at comparatively low figures. We have always from three to five hundred vessels seeking this coast for wheat freight from all parts of the world—principally from Great Britain, Australia and the East. They could easily be fitted out for passengers, whom they could carry at small cost.

The general Government should be urged to complete the survey of our forty millions of acres of unoccupied lands, so that an immigrant might know where to go, to pre-empt, or to select from. With these and such other arrangements as should recommend themselves it would not be long before we had a quite a large stream of immigration to this State. But not one cent should be devoted by the State to promoting individual schemes.

We hear, says the Colton Semi-Tropic, of some excellent finds of silver and copper ore in the mountains north of Frink's Spring, about 100 miles east of here.

point, except of late years, have such full statistics been preserved. The work commenced by the late Dr. Logan is now being continued by Dr. F. W. Hatch. The table explains itself, and the figures are brought down to the 14th of this month:

THE Contra Costa Gazette reports that S. B. Martin has sold his Santa Rita Rancho property in the Amador valley, comprising some 16,000 or 18,000 acres, at the rate of \$90 an acre.

Refining of Gold and Silver Amalgam.

(Written for the Press by E. N. RITTER.)

At a time when silver rates so low, and when especially there is so great a difference between the rates of discount on "low bars" and "fine bars," any contribution to our knowledge of how to make fine bars from low grade amalgam must necessarily interest the "milling public."

The following is the result of practical working on a large scale at the Anburn mill, near Reno, in 1874-75. Many crudities with which I then battled have been eliminated since by my experiments, and I do say that the process can now be carried out, even more successfully, both financially and chemically. What are the advantages of a simple, a cheap refining method for amalgam? Let us consider a mill producing silver of low fineness. There will be:

1. A saving in freight. Instead of shipping lead and copper at silver rates, it will enable us to ship nearly pure silver.

2. We would have much less retorting to do. Besides, the retorting of fine silver amalgam can be done faster and more perfectly than the retorting of base bullion amalgam. Especially if the base lead, the retorting is very slow and imperfect, the lead retaining quicksilver even after melting.

3. In many cases we might have a greater percentage yield of silver from the ore. It is a well-known fact to mill men that a greater yield is obtained by producing base bullion, but the consideration of "discount," etc., always makes him strive to produce fine bullion; finally the

4. And chief consideration, is the saving in "discount." The following are the prices ruling just now, as obtained from the chief bullion purchaser:

Average Prices of Bullion.

500 fine base lead, antimony and copper. 15% to 20% dis.	
500 fine base lead. 15% to 17% dis.	
500 fine base copper. 15% to 15% dis.	
750 fine base lead, antimony and copper. 15% to 16% dis.	
750 fine base lead. 14% to 15% dis.	
750 fine base copper. 15% to 14% dis.	
990 fine. 11% to 12% dis.	

Having thus made the large margin to the "refiner at the mill" so very apparent, I need not further enlarge upon the advantage to be derived, but will proceed to show how the refining can be done.

Chemical Principles Involved.

It had been known for a long time that when quicksilver becomes "fouled" by lead or copper, a slight shaking with bluestone and salt would thoroughly free it from these metals. Now, why not apply this same trick to amalgam? And, lo! the child was born!

Bluestone, $\text{CuSO}_4 + 5\text{H}_2\text{O}$, and common salt, NaCl , mixed in proper proportions will form copper chloride, CuCl (besides other compounds just now of no interest to us.)

This CuCl , very easily in cold or warm, thick or thin solution, takes up one more atom of copper or lead when brought in contact with either metal, forming sub-chloride (R_2Cl) or protochloride, in either case a whitish compound insoluble in water. It is true CuCl will also attack quicksilver and silver, changing them to chloride; but these metals are quickly reduced again to a metallic state, by a surplus of copper or lead.

All that is necessary to try the experiment is to take a quantity of base amalgam in a bottle, shake for some time with bluestone and salt, then wash out the grayish white insoluble sub-chloride (R_2Cl), and nothing but quicksilver and silver will be left.

Which is now the best way to apply these principles practically to the refining of amalgam on a grand scale?

In the following I will give "my way" as executed at Reno. At the same time I would say that perhaps other ways and other apparatus will do as well.

Apparatus Needed.

1st. I have a common Freiberg harrel, run by pinion and cog on friction gearing, so as to revolve about 18 to 20 times per minute. To refine one ton of amalgam, the harrel should be five feet by four feet in diameter, and made of three-inch pine staves, with a four-inch hole for a wooden hung. This harrel runs in a trough connected by a wooden conveyor.

2d. A deep settler also entirely of wood, with a tight-fitting cover. This settler is to be five feet in diameter, and five to six feet deep, with a solid wooden miller, geared to run 12 to 15 revolutions per minute.

3d. Large wooden vats to settle the wash water running from the settler.

Management of the Process.

We will now take a ton of amalgam, sample it thoroughly, and place it into the harrel, adding 500 to 600 lbs. more of quicksilver, so that it may be thoroughly thinned out. The sample we quickly test as to its percentage amount of Cu and Pb , and finding by Stoichiometrical calculation, that 100 lbs. $\text{CuO SO}_3 + 5\text{H}_2\text{O}$ will make 53 lbs. CuCl , and that consequently 2.12 lbs. CuCl will take up 1 lb. Cu ; 1.3 lbs. CuCl will take up 1 lb. Pb . I add enough bluestone to take up all the Cu and Pb , adding at the same time salt a plenty without further calculation.

Twenty or thirty cobble stones are put into the harrel, and enough wet pulp is added to

make a thick paste, and the harrel started revolving about 20 revolutions. After running a few minutes I stop to see that the temperature of the pulp is correct. A stick thrust in must bring up plenty of pulp, it must not drip thin from the same. Neither must it be so dry as not to adhere to the stick.

Now, start the harrel and run for an hour and vent; take a sample, and by straining the quicksilver, see how far the operation has progressed. If the quicksilver is coated with a dark skin, considerable time is still needed. If the skin is bluish-white it is near the finish; if entirely bright and clear it is finished. If run too long, (i. e., beyond the finish) the quicksilver will cut and settle very slowly. The process is not difficult to learn, a short experience gives you the exact time when to stop the harrel.

Just before the finishing point would have been reached, stop the harrel, and fill up with water, and again start the harrel, but this time only with 8 or 10 revolutions. This will allow the amalgam and quicksilver to collect and gather.

After half an hour's traveling stop and sample. Generally the charge is ready to discharge into the settler. If so, draw the bung, put in a wooden grate, so as to retain the cobbles, and turn the harrel hung down. Start the settler, hose out the barrel and conveyor rapidly (if possible with holed water, as this will prevent any chloride forming—however, this is not necessary), leaving the upper hung in the settler open, but the cover closed down tight.

I especially counsel that discharges and cleaning of the harrel should be done as rapidly as possible, as I found that the subchlorides (R_2Cl), on exposure to the air, immediately oxidize higher, forming oxychlorides ($\text{RO} + \text{RCl}$) and soluble chlorides (RCl), and that this newly-found chloride (RCl) will immediately attack the quicksilver, forming calomel, thus occasioning losses of quicksilver.

A continual stream of water is allowed to enter the settler (the washings are caught in tanks and allowed to settle), and the amalgam finally taken out by syphon and strained, etc. The settlings from the tanks are allowed to drain, shoveled by means of wood or copper shovels upon a platform (best of asphalt), moist-

which was brought down to about two ounces by slags, clips and other allowances.)

Our discount on 560 fine bars ranged from 12% to 14%, and on 990 fine bars the discount ranged from 8% to 9%.

In the extreme cases (8% to 14%) the saving in discount amounted to \$157 (\$230-\$73), in the other extreme (9% to 12%) the saving amounted to but \$33 (\$105-\$73.)

But I would again point out that I have placed the cost at its full value, if bluestone is bought as such. By transforming the Cu^2Cl to CuCl at the expense of the oxygen in the ore and sulphuric acid, the cost will be reduced more than a fourth.

Grooved Steel for Drills.

We show on this page engravings representing Sanderson's grooved drill steel for power drills. As will be seen from cuts above showing section of bar and drill, this steel is made in bars of the required shape for working end of what are commonly termed Barleigh drills. Heretofore this shape has been worked out from the octagon bars by hand labor, at a large expense, which, as will be readily seen from above cuts, is almost entirely saved by the use of this steel, the drills made from it being as readily and cheaply sharpened as hand drills made from octagon.

It is one-third lighter, though stiffer, than same size in octagon, and costs less per drill, though a small advance in price per pound is charged. It is easier handled in the mine, from its less weight; and the grooved form is found to clear the hole from debris better than the octagon.

This steel is now being used in several of the largest mines on the Comstock with great satisfaction, and has the unqualified approval of Mr. W. H. Patton and other mining Superintendents. In fact the advantages attending the use of this steel are so great and decided, particularly as to saving in cost of making and sharpening the drills, which amounts to fully 75% as compared with cost of drills made from octagon shape, that no mining company using power drills, can afford to continue the use of

POWER DRILL FROM GROOVED STEEL.

ened at intervals with very diluted sulphuric acid, when the copper can be gradually leached out as CuCl copper chloride, the same material with which we began. Thus, if our base was copper, we will soon have more CuCl than we need and copper for sale.

The residue may be rich in quicksilver, and can be added to the pans with advantage during the extracting of silver from ore, when all quicksilver will also be regained.

At the point above where we added pulp, a departure can be made. It is not necessary to add the pulp. The process is only very much shortened by this addition, or by the use of roasted copper ores. In case we have used no pulp, our residue will consist only of subchlorides. The copper can be extracted as before described, and the balance, being very small, can be restored when enough has accumulated, and the chloridized quicksilver thus regained.

The loss of silver is very small, never amounting to over 1%, and the most of this is recoverable, if the leached residue be added to the ore in the pans.

Instead of bluestone, where sulphureted copper ore is cheap, this can be roasted and used as indicated above, after having determined the amount of CuCl that will be formed by boiling the roasted ore with salt. I used this method very successfully at Reno.

Some other improvements in the process, that will cheapen and simplify the same, and upon which I am experimenting, I will describe in some future number of this paper. Giving the readers the figures of

An Average Charge

At Reno, I will close.

2,100 lbs. strained amalgam containing:—	
365 lbs. of $\text{Cu} + \text{Pb} + \text{Ag}$ (Ag would have been 560 fine).	
205 lbs. Ag.	
160 lbs. $\text{Cu} + \text{Pb}$.	
87 lbs. Cu .	
73 lbs. Pb .	

Coet.

388 lbs. bluestone	@10c	= \$38.80 to extract the copper.
176 lbs. "	@10c	= 17.60 " the lead.
200 lbs. salt	@1c	= 2.00 to finish the chlorine.
One man	@\$5 p.d.	= 5.00
Loss of Hg 6 lbs	@45c	= 2.70
Approximate loss of Ag 2 oz =		2.00

Total.....\$72.00

Yield was two bars weighing 3,010 ounces 988-99 fine, valued at \$3,846.78 (showing an apparent loss of about \$40 in refining, but

octagon steel. This steel will in all probability rapidly supersede the octagon in all such mines, there can be no question.

The following sizes, viz., one inch, one and one-fourth inch, one and one-half inch answering respectively for one and one-fourth inch, one and one-half inch, one and three-fourth inch drills, are found to cover practically the full range of use needed. Where larger than one and three-fourth drills are required, they are readily made from the one and one-half steel, by a little extra upsetting. A full line of this steel now for sale at the Sanderson's Steel Agency, 21 and 23 Fremont street, San Francisco, H. D. Morris, Sole Agent.

"NO TIME TO READ THE PAPER."—We occasionally hear of persons who state that they have "no time to read the paper." They might as well admit that they have no time to attend to their business. The manufacturer or merchant who neglects his daily paper does not know what the world is doing, and he who omits the perusal of his trade journal misses scores of seasonable and useful hints; is ignorant of what his home and foreign competitors are bringing out; takes no note of circumstances which, of no special moment in themselves, show which way the wind of commerce is blowing from time to time—and, in short, he overlooks a most important section of his business. The fact is, the man who means to be successful in business must read his paper, and must regard it as one of the features of the week. Without it he is kept in ignorance of what other firms are doing; is not posted up on all the changes of prices; has little intelligence from abroad, and that purely from his own agents' point of view; and only hears of his competitors' novelties when they have gained the market over his head. Pretty much the same set of remarks applies to the retailer, who, in neglecting his paper throws away every possible chance he has of buying to the best advantage and meeting the requirements of the public. Every trader must read his paper if he desires to be successful and make money. Next to his Bible should come his "trade organ"; with the two combined he need have little fears of the ups and downs of life and the whips and scorns of capricious fortune.—Ironmonger.

Tombstone District, Arizona.

EDITORS PRESS:—It was Solomon, I believe, who said, "there was nothing new under the sun." He certainly could have had no intention of including a mining district in his wise saying, and certainly not Tombstone district. There is something new every day here—new in the line of new discoveries and new strikes in the old mines. The Contention mine, for instance, quite recently astonishes everybody with a rich find of large nodules of chlorides in the lower workings, rich in silver and rich in gold, some of the specimens being literally covered with specks of gold.

But to drop from generalities and be more in detail, I will speak first of

Milling Facilities.

There is now one 10-stamp mill in operation, and two 20-stamp mills nearly completed, and a third and perhaps a fourth soon to follow.

The Tough Nut mine, located adjoining this town, is owned by a New England company, known as the Tombstone Mine and Mill Co. They have a 10-stamp water mill on the San Pedro river at Charleston, nine miles distant from the mine, that has now been in operation about five months. The first three months it was a dry crusher and turned out bullion at the rate of about \$60,000 per month. It has since been changed to a wet crusher, and now its yield is said to be, in round numbers, \$100,000 per month.

The Lucky Cuss mine, located about half a mile from the Tough Nut is also owned by a New England company, who are also erecting a mill (20-stamps, steam power) at Charleston, adjoining the Tough Nut mill. This mill will be in operation in about one month.

The Contention mine, owned by a California company, are putting up a 20-stamp mill on the San Pedro river, at a place called Contention City, 10 miles from the mine, which is located about one mile east of Tombstone.

The Empires mine, which also adjoins the town of Tombstone, was recently sold to a Boston company, who propose at once to put up a mill at Charleston. The Naumkeag mine, which adjoins the Contention, was recently sold to a California company, who also propose to put up a mill.

I do not intend to be enthusiastic over this country, but still will say that I believe there is no country on the top of this earth, of equal extent, that contains as many valuable mines and as much precious metal as can be found within a circle of 100 miles in diameter with Tombstone for the center.

Giving you a little geography by country, I will say that the Patagonia mines lie about 50 miles to the southwest; the Huachuca Mountain mines about 30 to 35 miles west of south; the Mule Mountain mines from 20 to 35 miles to the southeast; the Dragon Mountain mines about 15 to 25 miles to the northeast; the Limestone Mountain mines about 15 miles to the north; the Chisicahua Mountain mines from 35 to 40 miles south of east; the Doe Cabezas gold and silver mines 40 miles to the east, and the Arivaypa mines about 45 miles to the northeast. So you see we are surrounded by mines on all sides, the richest and most extensive in volume of rich ores being those that lie in the Tombstone mountains surrounding this place. New strikes of rich milling ores have recently been made in the San Jose mountains, just over the line, on the Sonora side. The future of this country is not known, but this is apparent to me that I have never before known a new mining country open up with such a bright beginning.

Tombstone town, or rather city, is already a place of more than 50 permanent residents, with all the miners from the adjacent mines to spend their nights, Sunday and money in the town. There are no less than 30 saloons already in full blast, at least a dozen stores, two lines of six-horse coaches running daily from Tucson; all lines of trades and professions, among them no less than eight resident lawyers; and what gives the strongest evidence of rush and prosperity is the two burdy-gurdy dance houses nightly filled, the keno games, besides a dozen or so other places where all kinds of gambling is openly carried on.

EDISON AND THE MINES.—The Oroville Mercury says: Major Frank McLaughlin telegraphed to us from Menlo Park, New Jersey, as follows: "Edison Ore and Milling Company is organized. Prominent New York parties back the scheme. Process for working tailings entirely new and Edisonian. All well." If anything were wanting to convince our readers that Edison intends to save the gold at present going to waste in the hydraulic mines of this section, the purport of the quoted dispatch undoubtedly removes the want. Very few of our readers appear to realize what an important item these works will be in the future prosperity of our city. None but the miners themselves, who have been saving not to exceed 40% of the gold contained in the dirt heretofore worked by them, seem to have the slightest conception of the marvelous results destined to be accomplished by this enterprise. It is a settled fact, however, that the works will be reared and in full blast within two months.

The San Jacinto Tin Mines.

During their recent visit to southern California the publishers of the PRESS took occasion to visit the San Jacinto (Temescal) tin mines. They were reached by a ride of about twenty-five miles westerly from Riverside. These mines are located in the Temescal mountains, which separate the upper from the lower Santa Ana valley. They are about fifty miles east from the city of Los Angeles and thirty-five from Anaheim landing. The existence of tin in workable quantities in the Temescal range has been known for twenty years or more; but the company now owning the property was organized January, 1868, and hold title by purchase of a Mexican grant of about 50,000 acres of land, upon which grant the mines are located. Active operations for opening up and developing the mines were commenced about six months after the company was organized, the most of the work being done upon the "Cajalco vein," which shows the largest ore croppings and the heaviest body of ore of any of the fifty or more distinct veins which are said to have been discovered and located upon this property. The roads to and from the mines are good at all seasons of the year, with water communication only thirty-five miles distant. There is an abundance of wood on the property for smelting purposes and for timber, and convenient water power sufficient for concentrating purposes. Lumber of all required dimensions, for mine, mill or building purposes, can be obtained from San Bernardino at a cost of from \$25 to \$30 per thousand.

We append herewith a diagram (Fig. 1) showing the boundary lines of the original grant of the Sohrante ranch, of about 50,000 acres, within which will be seen a square location of the tin district, which comprises the property of the San Jacinto Tin Company. It will be seen that the lower or western portion of the lands of the Riverside colony were embraced within this grant. In going to the mines from Riverside we passed through Magnolia avenue, as shown in the diagram, to its crossing of Temescal creek, from which point the road skirts along the western bank of the generally wide canyon through which the creek runs and which is thickly wooded and well watered, affording many sheltered nooks of arable land.

Concentrating Works.

The point where the Riverside irrigating canal empties into the creek has been selected as the site for the works which must be put up for crushing and concentrating the ores. The site is a most convenient one, with abundance of wood and water upon the spot, and where the supply of wood may be kept up perpetually from the rapid growth which, with a very little care, can be secured in this locality. It is also the very point at which the ore from the Cajalco and several parallel veins can be most conveniently delivered through an adit tunnel, which will strike the veins at a great depth, running in from the eastern bank of the creek canyon. The road, after passing along up the canyon a distance of some three miles, turns suddenly to the left and climbs the high hilly region in which the mines are located. After passing the works upon the Cajalco vein the road continues on to the plains beyond, as indicated, and so back to Riverside. The road to Anaheim landing continues westerly in nearly the same direction as Magnolia avenue, joining that avenue at the crossing of Temescal creek.

Developments in Progress.

Fig. 2 gives a sectional view of the work of development upon the mines. As will be seen two shafts have been sunk 77 and 93 feet in depth. An adit tunnel has been driven in, following the course of the vein from a ravine, as shown in Fig. 2, to a distance, in one direction, of 449 feet, and about 100 feet in the other direction. The first 100-ft level has been opened for a distance of 375 feet, and is connected with the adit level by the main shaft and also by a winze. The hoisting has thus far been done by a horse whim, of which there is one for each shaft. The shafts and tunnel and hoisting works appeared to be all in good condition at the time of our visit, although filled by water up to the drain level. No work has been done upon the mines for some time, the present owners waiting for capital wherewith to commence operations on a scale commensurate with the value and importance of the mine.

A large amount of rock has been raised to the surface—sufficient to show, quite conclusively, the general character of the ore. Several shipments, of several tons each, have been made to

this city, and, we believe, also to England, which have been worked with most satisfactory results. Considerable work has been done upon other ledges in the way of sinking pits and shafts to determine the locality and extent of veins. The work upon the mine has been under the supervision of Mr. Williams, a Cornwall tin miner of thirty years' experience, who expresses the fullest confidence in the great value of the property.

The mine was visited and examined some four or five years since by Mr. N. M. Maxwell, an English engineer, and at that time, if not now,

from the tin mines of Cornwall, at a cost of working in excess of what would be the cost here, by reason of the low percentage of the ores there, the great depth at which the mines are worked, and the scarcity of wood and water. Ore can be profitably raised there at this time from only the richest of the mines. Travelers through Cornwall inform us that hundreds of tall chimneys may be seen in almost every direction looming up as silent monuments of mines worked out, evidences of busy life long past. That the tin deposits of Cornwall are fast becoming exhausted; that they will con-

the Temescal hills? We leave it for others to make the figures.

Tin Statistics.

Statistics giving the true amounts of the tin production of the world are very difficult to obtain, as nearly all interested in the business strive to keep the particulars of the same as much a secret as possible. Johnson, in his recent encyclopedia, perhaps the best authority at hand, gives the figures for the production of tin in 1871 as follows:

England.....	11,320 tons.
Spain.....	4,350 "
Bolivia.....	3,190 "
South America.....	1,200 "
Other sources.....	5,000 "
Total.....	25,030 tons.

The consumption of tin has ever been close upon its annual yield. There is seldom, if ever, any large surplus, and the increasing uses to which it has been applied during the last few years is steadily adding to the annual demand for it.

The process of obtaining tin from the ore is very simple and comparatively inexpensive. The mineral occurs only in two forms—the oxide and as a sulphuret, never native. The oxide occurs in compound octahedrons and square prisms, with various modifications; it is nearly opaque, and gives a pale brown streak. In this form, when pure, it yields 78.33 tin. The sulphuret forms in cubes of a yellowish gray, giving a brown streak, and yielding tin 27%, copper 30%, sulphur 30%, and iron 13%. Tin is almost always associated with copper. The tin mines of Cornwall have in many cases been worked for copper when first opened, the tin coming in generally at about 1,000 feet in depth. The San Jacinto ore is remarkably free from many mineral impurities which greatly trouble the smelters of Cornwall, and as a consequence yield a much purer metal. This fact has been noticed by tin workers who have worked up the small amounts of tin which have from time to time been obtained from these mines.

NATIONS look to the United States for their supplies of food, and yet few people realize the great productiveness of the soil in this country. Some recent statistics showing the quantity and value of our principal agricultural products for the past ten years will therefore interest many of our readers. As prices are low and production large, the yield in money for cereals this year may be less than the average. The average per year—home values—for ten years is given in the following table:

	Bushels.	Value.
Corn.....	1,088,959,550	\$526,211,002
Wheat.....	273,831,746	301,481,540
Rye.....	18,016,030	15,091,207
Oats.....	291,036,670	110,810,591
Barley.....	30,606,609	25,385,459
Buckwheat.....	10,938,070	9,204,801
Hay.....		300,000,000
Cotton.....		200,000,000
Total.....	1,692,388,675	\$1,553,175,201

Butter products this year will be worth about \$170,000,000; cheese and milk, \$130,000,000; beef and its products, \$270,000,000; pork and its products, \$250,000,000. The increase for this year in the production of cereals over the average of the last ten years is estimated at about 28 per cent., and it is thought by some that the aggregate value will not be greater; but taking ruling prices as a basis for calculation, and allowing a margin for lower prices during the remainder of the crop year, we believe that the average value given will be greatly exceeded.—American Mail and Export Journal.

ADULTERATION OF LIME JUICE.—It is said that the lime juice sold in London and in Australia has been found so adulterated with sulphuric acid that it is injurious instead of wholesome as lime juice is in its natural state. This adulterated juice purports to be from the South Sea islands. If the exporters thence do not stop such operations there may be a good chance for price enough to make pure California lime juice a profitable product.

LOWER CALIFORNIA MINES.—The San Diego News says that the gold mine of Gov. Castrejon, located near San Rafael, is being worked and is yielding well. The character of the vein has not been determined. It may be a pocket or a ledge. The first little division found, yielded \$600 in a little while.

COLONEL BROADHEAD, of San Francisco, has bought the Pilgrim mine, in the Sawtooth mountains, Utah, the consideration being \$25,000.

FIG. 1. DIAGRAM OF THE SAN JACINTO TIN MINING DISTRICT.

manager of the Flagstaff mine in Utah. Mr. Maxwell has spent many years in the tin mines of Cornwall, and is pronounced one of the best practical experts in tin mining who has visited this coast. He made a thorough examination of the mine, which was being worked at the time, and free from water, and reported to the expert of the company that he believed that the mines of this company contained more tin than existed in the whole of Cornwall.

If we can place confidence in the opinion of experts, there is tin enough in these mines to supply the entire demand for that metal in the

tinne but a little longer to add their annual contribution to the material wealth of the world, is now very generally conceded.

Other tin districts of the world are worked to about their fullest capacity, and it would seem to be the part of wisdom for California to step in at this time and contribute her share, as she may do, to this important industry.

Comparative Value of Mines.

A tin mine in Cornwall that pays 2% is considered a good property, with, if an extensive one, "millions in it." The Levant mine is

FIG. 2. SECTIONAL VIEW OF THE CAJALCO MINE.

United States—a supply which is now furnished from abroad at a cost of from twelve to fifteen millions annually. Tin is one of our largest articles of import. Its uses are numerous and vast, and the consumption very great. Why not turn this large balance of trade in our favor? Our capitalists should feel a national pride in the matter, and should be ready to aid with their means and influence in so useful and important an undertaking. The working of these mines on a proper scale would add thousands to the population of this State, and millions to the aggregate of our productive industry. England has for centuries reaped rich returns

worked to a depth below drainage of 1,800 feet, and yet yields an average of only 2 1/2%. The Dolcoeth mine, also at a depth of 1,800 feet, yields only 2% ore. Tailings are worked over at that mine that yield only one-quarter of one per cent. of concentrated ore. The Phoenix mine, near Siskeard, one of the best managed mines in Cornwall, is worked at a depth of 1,500 feet, and yields only 1%, and yet the property, depleted as it is, is valued at \$1,200,000. When, in contrast with the above, we take the estimates of Cornish experts that the Cajalco mine will yield an average of 5%, what must be the value of the wealth of tin buried in

Spruce Mountain Mines.

Difficulties Which Have Been Overcome.

EDITORS PRESS:—Permit me, through the medium of your valuable columns (for the benefit of many who have been misled and by misrepresentation caused to believe that which was false), to state that six long years ago war was declared against the inhabitants of Spruce mountain by a set of unprincipled beings, who fortified themselves on the east end on the west, and opened their batteries upon us and all others who might by chance express a desire to locate among us, and by their representations have persuaded nearly all to shun us and locate elsewhere. Their object in so doing was to cut off our communications and supplies, thus leaving us destitute and alone, thinking that in time we would be compelled to abandon all that we held by right of discovery and possession; that they might without further effort inherit the lands and wealth of others, and then dictate to them terms most unreasonable, and no less than an unconditional surrender. Such terms were contemplated and frequently made known in public boasts, but such terms have been and will be as frequently rejected with a determination to fight it out on our own line.

The war waxed warm. Skirmishing in the back grounds has been of frequent occurrence, and many a poor warrior fainted and fell by the way; but a few of the surviving brave who remained to fight the battles of life retreated into the Black Forest of the mountain, and have there successfully defended and protected their poets and monuments, marking the discovery and boundaries of the land which they claim. During those years the men in the camp have amused and buoyed themselves by developing the mineral wealth that lay within their forest bounds, and are now ready to advance into open field and demand their right to admittance into the great American "mineral boom," on the merits of the once hidden but now developed treasure that lies waiting only the hand and capital of intelligent men to claim its place in the kingdom of coins.

There are in this district thousands of tons of free smelting ore developed that will average 40% lead, and from 40 to 50 ounces per ton in silver. This ore can readily and cheaply be converted into coin, as shown by the following itemized estimate in mining, hauling and smelting, being but one 30-ton furnace and six coal kilns, which can all be built in this camp at a cost not exceeding \$15,000, thus:

1. Wood can be bought and delivered at the kiln for a long time at a cost not exceeding \$5 per cord.	
2. One cord of wood will yield 45 bushels of coal, which amounts to 11 cents a bushel. The cost of burning said coal is about 1½ cents per bushel, making total cost of coal 12½ cents per bushel.	
3. Twenty-five bushels of coal will smelt one ton of ore, and 750 bushels will smelt 30 tons of ore, which will, at 12½ cents a bushel, amount to.....	\$93.75
4. Cost of labor, wood, oil, lights, etc., per day, as follows:	
2 engineers @ \$4.50.....	9.00
6 smelters @ \$4.....	24.00
3 feeders @ \$4.50.....	13.50
3 ore crushers @ \$3.50.....	10.50
3 ore wheelers @ \$3.50.....	10.50
3 coal wheelers @ \$3.....	9.00
1 roustabout @ \$3.....	3.00
1 blacksmith @ \$5.....	5.00
1 Superintendent @ \$10.....	10.00
3 cords of wood for engine @ \$5.....	15.00
Oil, lights, etc., @ \$5.....	5.00
Total cost of smelting per day.....	208.25
Divide \$208.25 by 30 (tons of ore), and you have the cost per ton, which is \$6.94.	
5. Cost of mining will not exceed \$1.50 per ton and 30 tons will cost.....	45.00
Hauling ore to furnace at 50 cents per ton.....	15.00
Total cost of mining, hauling and smelting.....	\$268.25
Total cost of mining, hauling and smelting per ton \$8.94	
6. Three tons of ore will average a yield of one ton of bullion.	
Total cost of bullion per ton at furnace.....	\$26.82
7. Freight on bullion to R. R., per ton.....	8.00
Freights by R. R. to N. Y., per ton.....	40.50
Total cost of bullion per ton in market.....	\$75.32
8. Lead value of bullion in market at 54¢.....	\$110.00
This shows a net profit on lead, per ton of bullion of.....	34.78
And a net profit on lead, per ton of ore, of.....	11.59
9. The silver value contained in each ton of bullion or ore is an additional net profit, which will amount to about \$145 per ton of bullion, or about \$48.33 per ton of ore.....	48.33
Making a total net profit, per ton of ore, of.....	\$59.92

I believe the above estimate to be within bounds and reliable, as most of the above figures upon which the estimate is based were obtained from reliable and experienced men in the business, such as Mr. Franz Jungk, of the Germania Smelting Company, Utah, and Mr. N. R. Remley, of Utah, a man of practical experience in building coal kilns and in burning coal; also from expert miners who well know the ease and cheapness with which ore can be mined and delivered at furnace in this district. Taking into consideration the quality and quantity of ore that has been developed in this camp during the last two years, and the natural facilities for working the mines, reducing the ore and freight to the product to market, I am conscientious in saying that there is not a mining camp in this or any other State or Territory holding as many natural advantages and equal inducements for capitalists as can be found here at the present time; and as soon as any party with sufficient capital, energy and intelligence takes hold of the mines in this camp the name and merit of this district will be sounded

abroad. For the benefit of those wishing to visit and examine the mine in this camp, I will state that this district (Spruce Mountain) is situated 35 miles south of Wells' station, a town on the Central Pacific railroad, in Elko county, Nevada, and is connected with Wells by a tri-weekly stage. "Sprucemont" is a small town situated on the west side of Spruce mountain, near which are several good prospects and mines, namely, the Iroquois, Milo, Evening Star, St. Louis, Eureka, Carry and Great Expectation. The Iroquois is now being worked, and turning out ore that will assay from \$200 to \$400 per ton. The Milo has about 100 tons of good ore on the dump, and shows good bodies of ore in the shaft. It is 180 feet deep. The Evening Star has about 50 tons of ore on the dump that will assay 50% lead and \$60 in silver; the Eureka and Carry have about 100 tons of ore on the dump, and show considerable more in the mine. Two and a half miles northeast of town and on the main mountain, are situated the Juniper, Keystone, Killey, Badger, Eva, Havana and Monarch mines. The Juniper is developed by tunnel, incline, drifts and shafts to a depth of 150 feet. It shows large bodies of good ore and is evidently the making of a big mine. The Killey is developed by shaft, tunnels, cut, incline and drifts, to a depth of 150 feet, and shows large bodies of low grade ore and a little good grade ore, and would probably make a good mine if properly managed and developed. The Eva is developed by incline to a depth of 40 feet; it shows a well-defined vein of ore varying from six inches to two feet in width, and there is about 25 tons on the dump.

One-half mile east of the Killey are located the Black Forest, Brietol, Cave and London mines. The Black Forest is the chief, and is developed by tunnels and inclines to a depth of about 340 feet; it shows large bodies of free smelting ore from within 20 feet of the surface to the lowest level. The amount of ore developed in this mine is estimated at about 10,000 tons, and there is six or seven hundred tons of splendid ore out on the dump; and judging from the general appearance of the mine, I believe that by extracting the ore now uncovered, a bonanza of immense value will be developed. The ore in this mine shows by assay, an average of 40% lead and about \$50 per ton in silver.

There is, undoubtedly, enough ore developed to insure a long and remunerative business in smelting. One-fourth of a mile east of the Black Forest mine is plenty of water and a splendid furnace site, connected with the mine by good road over which ore can be hauled at all times of the year for 50 cents per ton. There is abundance of timber on the mountain for mining and building purposes, and the adjoining foothills are heavily timbered with nut-pine, cedar and mahogany, suitable and convenient for coal purposes. OLD 49ER.

Wells, Elko Co., Nevada, Dec. 13th, 1879.

Buelow Mine, Nevada County.

Among the many valuable mines of Nevada county, the *Herald* of a recent date selects the Buelow mine, as of special interest. The mine is about eight or nine miles west of Nevada City and is located on a hill situated in the bend, and south of the South Yuba river, just opposite French Corral. About two years ago an incline was sunk on this ledge about 75 feet deep, and the ledge averaged about eighteen inches in thickness. A year ago a new shaft was sunk about thirty feet from the mouth of the first shaft, to determine whether the ledge was continuous, and the ledge was found to be about twenty-two inches thick on an average. After sinking down about 40 feet, an incline was started from the bottom of the shaft and extended down a distance of 160 feet, the ledge averaging about the same thickness the entire distance. The water commenced to rise and filled the bottom of the incline for a depth of about 40 feet, when it became stationary, and work was resumed by commencing to run a drift on the ledge just above water level. The drift has been driven ahead 30 feet, and the men are pushing it ahead. The incline will not be sunk any deeper at present, as it would require the erection of more extensive appliances to control the water. The ledge runs east and west. Mr. F. Manegold is the foreman of this enterprise and very kindly explained everything to the reporter.

The prospects in this mine are very bright, being a fissure vein much can be expected. The ore is a rich arsenical, carrying a black and red oxide of copper. The copper sulphurets run as high as 45% gold. The average per ton when worked by mill process is \$50. The decomposed arsenical ore near the surface shows free gold in many places. There is a large quantity of ore in eight and we understand that work is to be pushed. The owner has put up new buildings and made other improvements. The owner is using a whim at present for hoisting purposes. A tunnel run in 500 feet will give 600 feet of depth of vein and drain the mine. We understand that it is proposed to run this tunnel south. There can be no doubt from all indications, that the mine will form a permanent and profitable piece of property. Work is being vigorously prosecuted at present to effect a thorough prospect, so as to determine the amount of ore and the extent of machinery which the owner will be justified in erecting.

ACCORDING to the Salt Lake City Treasurer's report, it cost \$157,372.96 to run the city government one year.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 202 SANSOME ST., N. E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurttemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawing and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communication and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

UNITED STATES

Mineral Land Laws, Revised Statutes

AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or Absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

READING RANCH,

Shasta Co., Cal.

Good Land!**Sure Crops!****HEALTHY CLIMATE!****Prices Low. Terms Easy.****TITLE PERFECT.****LAND FOR SALE OR RENT IN SUB-DIVISIONS.**

The Reading Ranch, in the Upper Sacramento valley, originally embracing over 20,000 acres of choice grain, or charcoal and pasture land, is now offered for sale at low prices and on favorable terms of payment, in subdivisions to suit purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drought.

The climate is healthy and desirable. The near proximity of high mountain peaks give cool nights during the "heated term" which occurs in our California summers.

Pasturage, wood and good water are abundant. The tillage land is mostly level, with complete drainage.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract without irrigation. Also, Alfalfa, Vegetables, Corn and all other cereals ordinarily grown in the state.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The title is U. S. patent. Prices range principally from \$5 to \$30 per acre.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading, all of which are located within the limits of the ranch.

The Sacramento River borders the whole tract on the southeast. Its clear waters are well stocked with fish. Good hunting abounds in the surrounding country.

Producers have a local market, which enhances the value of their produce. The railroad transportation route is level throughout to San Francisco. A portion of the land is auriferous and located near rich mines now being worked. Land suitable for settlers in colonies can be obtained on good terms.

Town lots are offered for sale in Reading, situated on the Sacramento river, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor.

EDWARD FRISBIE,
Anderson, Shasta Co., Cal.
P. S.—Send postage stamp for illustrated paper containing information about Shasta county and these lands, and say advertised in this paper.

Location of Shasta County.
Shasta County lies not far from midway between the two most important ports on the Pacific shore, i. e., San Francisco and Portland, Oregon, and directly on the overland route, which in the future will become the grand thoroughfare from Mexico to British Columbia. The town of Reading, at present, and probably for years to come, the head of railroad transportation on the California side of the mountain intervening below Oregon, is distant from San Francisco by railroad (via Vallecito) 256 miles; from Sacramento City, 160 miles; from Marysville, 117 miles.

Persons thinking of buying or renting land will not likely regret a camping or excursion trip to this upper Sacramento country.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the
Extraction of their respective Metals without Quick-
silver. 1870.
This rare book, on the treatment of gold and silver ores
without quicksilver, is liberally illustrated and crammed
full of facts. It gives short and concise descriptions of
various processes and apparatus employed in this country
and in Europe, and explains the why and wherefore
It contains 142 pages, embracing illustrations of fur-
naces, implements and working apparatus.
It is a work of great merit, by an author whose reputa-
tion is unsurpassed in his specialty.
Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including
the Chlorination Process for Gold-bearing Sulphurets,
Arsenurets, and Gold and Silver Ores generally, with
120 Lithographic Diagrams. 1867.
This work is unequalled by any other published, embrac-
ing the subjects treated. Its authority is highly esteem-
ed and regarded by its readers; containing, as it does, much
essential information to the Miner, Metallurgist,
and other professional workers in ores and minerals, which
cannot be found elsewhere in print. It also abounds
throughout with facts and instructions rendered valuable
by being clearly rendered together and in simple or
gauges and other valuable means. Elegantly printed
on extra heavy paper. Subscription price, \$1.50. Orders for
first edition received now.

The Multiplex Copying Tablet.

This is Something New and Valuable.

By simply writing with copying ink any number of good
plain copies up to 100 can be produced with great speed.
It is a great and remarkable improvement. It is manu-
factured by WILLIAMS & BOURNE, 612 Clay St., S. F.

Letters which Speak for Themselves:

SECRETARY'S OFFICE, WELLS, FAROE & CO.:—Gentlemen:
—I have tried your Multiplex Copying Tablet, and can
cheerfully say that I have found it very much superior to
three or four of the same processes which I have experi-
mented with, and it is the best I have seen.
Yours truly, CHARLES W. BAKER.
San Francisco, Nov. 17th, 1879.

OFFICE CHIEF OF POLICE:—Gentlemen:—In reply to your
request to give my opinion of your Multiplex Copying
Tablet, which has been in use in this office for some time,
I would say that it works easily and rapidly, performs
good service and gives perfect satisfaction, being superior
to anything of the kind used heretofore.
Yours Respectfully, JOHN KIRKPATRICK,
San Francisco, Nov. 13th, 1879. Chief of Police.

The MULTIPLEX is superior to all others for the fol-
lowing reasons:
First.—It will produce a very sharp and clean copy, and
over one hundred impressions may be taken with excel-
lent result.
Second.—After copying, THE INK MAY BE WASHED
FROM THE TABLET ALMOST INSTANTLY.
Third.—The composition is put up in a neat wooden box,
properly lined, and is not so readily affected by climatic
influences.

PRICE LIST:

ALLEN GOVERNOR.

Most Perfect Engine Regulator in Use.

And will in most cases save its cost several times a year.
It is invaluable on a QUARTZ FLOUR or SAW MILL
ENGINE, or in any Manufacturing Establishment, where
Regularity of Speed is desirable. By being able to run
the engine to its full capacity, these Governors have in
many cases added

Ten Per Cent. to the Produc-
tive Capacity of a Mill,

Thus saving more than their cost every week in the
month. Every Engine to which this Governor is attached
will run with the throttle wide open. The speed of the
Engine can be changed by a simple adjustment of the
weights. It will give a UNIFORM SPEED WITHOUT
REFERENCE TO THE BOILER PRESSURE. It is simple
in construction and not liable to get out of order.
Every Governor warranted to give perfect satisfaction.
Thirty days given for a trial, and if it does not fulfill all
that is promised, it can be returned at our expense.
In ordering, state the kind of engine, diameter of cylin-
der, stroke, speed, and average pressure.
Send for full descriptive circular.

PHOSPHATE SOAP

THE BEST soap for toilet use ever
manufactured. BEST because it con-
tains all the excellencies of the most
expensive foreign or American soaps
without their defects. BEST because
it combines strength with delicacy
in such a way that its strong deterative
qualities do not injure the skin.
BEST because it is the result of years
of study and experiment in the soap
manufacturing business, assisted by
modern chemical discoveries. BEST
because it contains ingrediente bene-
ficial to the skin, which unite chemi-
cally with the soap in such a manner
as to increase its saponaceous quali-
ties. Every chemist familiar with
soap manufacture knows that some
ingredients which are in themselves
beneficial to the skin cannot be saponi-
fied; some are partially neutralized,
while others injure the quality of the
soap. There are soaps in the market
which are to some extent beneficial to
the skin, but they are inferior articles
for toilet use. PHOSPHATE SOAP
is the ONLY article offered to the
public which combines all the best
elements of toilet soap with medical
ingredients beneficial to the skin.

If you wish to make your hands
soft buy a cake of PHOSPHATE
SOAP, and when that is gone you will
buy a dozen and recommend your
friends to do the same.

Ladies who wish to make the skin
look beautiful and natural should use
PHOSPHATE SOAP.

For chapped hands the constant use
of PHOSPHATE SOAP will be rec-
ommended by all who give it one fair
trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879,
To the Standard Soap Co.—Gentlemen:
It affords me pleasure to say to
the public that I have used and pre-
scribed your PHOSPHATE SOAP
as a remedy in various forms of
cutaneous diseases with the hap-
piest results. I am of the opinion
that it is the mildest and most per-
fect detergent that can be used,
either for cleansing the skin and
leaving it soft and healthy, or for
removing the fetor and corroding
influences of sores and ulcerations.
I should be sorry to be without it
in shaving my face or making my
toilet, to say nothing of my good
opinion of its remedial qualities.
A. J. SPENCER, M. D.,
SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:
I received a package of your soap
(Phosphate Soap) and it gives me
great pleasure to testify as to its su-
perior excellence. As a toilet soap I
have never seen anything to sur-
pass it. It also possesses superior
remedial qualities. I have used it
in two cases of obstinate skin dis-
ease, one of intolerable itching,
Pruritus, the other an Eczema. In
both great relief was obtained.
Its emollient properties are remark-
able. Respectfully,
W. A. DOUGLASS, M. D.,
126 O'Farrell St.

To the Standard Soap Company.
SAN FRANCISCO, July 19, 1879.
Standard Soap Co.—Gents:
I have tried your PHOSPHATE
SOAP, and have no hesitation in
saying that it is the best toilet
soap I ever used. My wife has used
it and is of the same opinion. I
have paid as high as fifty cents per
cake for an article in every respect
inferior to what you sell for twenty-
five cents. HENRY H. LYNCH,
515 Haight street.

The genuine merits of PHOS-
PHATE SOAP and persistent ad-
vertising will force every druggist,
groceryman and general dealer to
order it by the gross sooner or later.
Ask for it in every store. The re-
tail price is 25 cents per cake. We
wish to sell it only at wholesale, but
in case you cannot find it we will
send a nice box of three cakes by
mail, postage paid, on receipt of 85
cents in stamps.

Channel Street, off foot of Fourth, San Francisco.

Highest price paid for Sulphurets, Arsenurets, Tellurides and Gold Ores generally.

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-plumbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotypes plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SCIENTIFIC PRESS ENGRAVING CO.,

No. 202 Sansome St., S. F.

PATENT

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS AND GEARING, specialties. Circulars and Price List free. Address CHESTER STEEL CASTINGS CO. Works, CHESTER, Pa. - 407 Library St., PHILADELPHIA.

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Mining & Scientific Press

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special spheres unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 72 pages and 83 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Postpaid, \$10.50. Sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated. 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Postpaid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Postpaid, \$1.00. Sold by Dewey & Co., S. F.

PALACE RESTAURANT

This elegant and spacious S. F. Restaurant has been re-opened with superior bill of fare daily.

Good Living at Reduced Prices

218 Sansome St.

ly, and is now the best and most popular dining saloon on this Coast. [Lunch ready at 10 A. M.] Resident business men and visitors from abroad will be wise in giving this place an early call. Examine bill of fare and prices.

HERMAN H. HORST, Prop'r.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this Coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

FRASER & CHALMERS
STEAM ENGINES, BOILERS, STAMP MILLS, CRUSHERS
(and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.
No. 145 Fulton St. CHICAGO, ILL.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

BEST REFINED CAST-STEEL.

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock, and for sale at

21 and 23 Fremont Street, S. F., - H. D. Morris, Agent.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed under-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouing or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

In consequence of spurious imitations of
LEA AND PERRINS' SAUCE,
which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine. Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

Engraving.

Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the Mining and Scientific Press, San Francisco, at favorable rates.

PETERSON & OLSSON, MODEL MAKERS.

INVENTORS

Will find it to their advantage to call on us at 323 BUSH STREET, bet. Montgomery and Kearny, (up-stairs), S. F.

FOR SALE, CHEAP.

Second-hand Varney Rock Breaker, large size. J. W. Riley, 56 Bluxome St., San Francisco.

Boxing, from \$5 to \$8 extra. Delivered on Cars. Burns Hard or Soft Coal.

Scott & Eckart Automatic Slide Valve Cut-Off Engine, over 60 now running and giving perfect satisfaction in every respect.

They have bought the patent right of, and perfected the BREWSTER ENGINE AND BOILER, Which is a single-acting Engine whose valve is moved with the piston rod, thus dispensing with the cost and expense of eccentric, etc. This very valuable invention is now offered to the public as a First-class Cheap Engine.

Semi-Portable Hoisting Engines, with or without Locomotive Boiler, from 8 to 12 inches diameter of cylinder.
Vertical Baby Hoisting Rigs—double engines, compact, cheap and portable, from 4 in. to 8 in. diameter of cylinder.
Horizontal Baby Hoisting Rigs—do. from 4 to 10. in. diameter of cylinder.
Vertical Engines and Boilers of all sizes on hand, from 4 in. diameter of cylinder up to 12 in. diameter of cylinder.
Horizontal Engines from 8 in. diameter of cylinder up to 24 in. diameter of cylinder, ready to ship at short notice.
The O'Neil Balanced Valve Automatic Engine, with improved Governor, equal as a fuel saver to the best.

SCOTT & ECKART'S IMPROVED AIR COMPRESSOR,

With Scott's Patent Air Valve and Eckart's patent piston and water jet, combined with every improvement in compressing air up to date. The record of our Air Compressor we refer to with pride, and know that this Machine will compress air with less power and water than any now built.

National Air Compressors. Delamater's Air Compressors.

THE ECLIPSE CRUSHER

We have introduced as being a great improvement of any heretofore built. We manufacture 4 sizes, namely: Class A, 10 x 16; Class B, 8 x 13; Class C, 7 x 10; Class D, 4 x 7.

THE ECLIPSE ORE FEEDER

Having a positive feed, will feed wet or dry materials, coarse or fine, is simple in construction and cheap. Made to order to suit any size or condition of Battery.

ECLIPSE PAN,

Combining all the modern practices up to date and mechanical improvement, dictated by sound metallurgical experience, covered with five separate patents, is acknowledged the Ne Plus Ultra of Amalgamators.

Call and Examine before Purchasing Elsewhere.

Lodes and Ore Deposits.

Deposits formed by Alteration of Granite.

At a meeting of the Geological Society of London not long since, C. LeNeve Foster, Esq., read a paper "On the Great Flat Lode south of Redruth and Camborne, and on some other Tin Deposits formed by the Alteration of Granite." This paper is specially interesting as showing the probable mode of origin of the lode and the consideration given to the question of the alteration of granite. In order, however, to have a clear idea of the general conclusions reached, some details of the different mines of the lodes will have to be studied, and we take the liberty of making the following condensation or abstract of the first part of Mr. LeNeve's paper, leaving for a future issue that part which relates to the general principles involved.

The hill called Carn Brea, in West Cornwall, near Redruth, forms part of a mass of granite about four miles long, in a direction E. 30° N., generally about five furlongs wide, but terminating both east and west in a long narrow tongue. The granite is surrounded on all sides by the so-called killas or clay slate. To the north of this hill are numerous famous mines, and to the south, again, mining operations have been carried on to a considerable extent. It is some of these latter workings which Mr. LeNeve describes, and which he thinks possibly form part of one great mineral vein stretching for more than three miles from Persseverance mine on the east to South Tolcarne on the west. The continuity or non-continuity of the deposits is not a question which affects the purpose of the paper, the main object of which is to point out how the mineral repositories in question differ from those which are included in the ordinary definition of a lode or mineral vein.

Wheal Uny, a section of which at the 130 fathom level is shown in Fig. 1, is entirely dependent on the Great Flat lode. It dips about 46° south, and is much flatter than veins usually are in Cornwall, where 70° is the average dip. A peculiarity of the lode in this mine is that it lies at the very junction of the granites and killas, and if looked at by itself might be considered an example of "contact deposit." However, as the workings to this west show a similar lode or clean granite, it is evidently not necessarily connected with any phenomenon due to contact of dissimilar rocks. In the Fig., A shows the "leader." It is in one part 18 inches wide, consisting of a mass of fragments of more or less altered killas (capel) with some tin oxide, and it soon dwindles down to a mere *flucan* or vein of clay, with a little quartz only two inches wide. The sides (walls) are very smooth, presenting numerous slickensides; in fact this leader has all the appearance of a mere crack, filled in the main mechanically by fragments of the sides reduced in places to a clay by the attrition of the walls. B is the lode, a very fine grained, bluish-gray schorl-rock, with little spots or strings and veins of quartz, cassiterite, chlorite and iron pyrites. B is a schorl-rock, known as "grayback," with large grains of quartz in a compact black matrix, not separate from B by any distinct line. E is hard, compact capel or schorl-rock. The killas, F, to the south, and granite, G, to the north, are rarely seen during the workings in the lode. The crosscuts have proved that there is no wall or definite place of division between the *gray-back* and the granite any more than there is between the *gray-back* and the lode, nor is there any straight line of demarcation between the killas and the capel.

As may naturally be supposed the lode varies greatly in character. Sometimes the tin-bearing rock is above instead of being below the leader. At the South Carn Brea mine, west of Wheal Uny, the same lode was followed down 175 fathoms, mainly between the granite and killas, with the same general features. There was this difference, however, the narrow leader being a copper lode 2 to 4 feet wide, as shown in Fig. 2. In this figure, A, is the copper lode; B, C, more or less stanniferous schorl rock—that is, lode and capel; E is the schorl rock (derived from killas); F is the killas, and G granite.

The Wheal Basset lode was originally started

as a copper lode, but eventually the Great Flat was intersected, and it is to this vein that the mine is now indebted for the greater part of its produce. The lode is now entirely in granites, and the section shown in Fig. 3 of the workings above the 104 fathom level will explain its character. A is the leader, a red ferruginous clay vein with fragments of capel of 2 to 3 inches thick. B, C, lode and capel, that is, stanniferous and non or slightly stanniferous schorl rock, nine feet thick above the leader and six feet thick below. There is no wall between this lode and capel, nor between the capel and granites, G, G. The stanniferous part has usually a grayish bluish color, and is a compact rock, with veins and spots of quartz and cassiterite. The schorl rock, with large grains of quartz in a compact black matrix, is invariably unproductive.

At South Condurrow, the Great Flat lode is entirely in granite, though the thickness of the rock on the hanging wall in the upper part of the mine must be small. The general features of this lode are much the same as in West Basset—a narrow leader, with lode and capel above it. The tin-bearing part averages five or six feet wide, and the lode and capel together will quite make up 12 feet.

Fig. 4 shows a section of South Condurrow,

Fig. 1. Section of Lode at Wheal Uny.

Fig. 2. Section of Lode at South Carn Brea.

Fig. 3. Section at Wheal Basset.

Fig. 4. Section at South Condurrow.

TIN MINES ON GREAT FLAT LODE FORMED BY ALTERATION OF GRANITE.

above the 93 fathom level, in which A is the leader. B, the lode, C, the capel and G, the granite. The tin-bearing part here is above the leader.

In many places the Great Flat lode contains a great deal of chlorite, some iron pyrites and kaolin. Occasionally kaolin fills up the cavities in the quartz veins. There is no wall or separation between the capel and granite or wall and capel, the passage is gradual.

Mr. LeNeve says he proved the wall and capel were really schorl rock, by the blow-pipe and microscope. The blow-pipes showed evidence of much boron, and subsequent tests revealed the existence of fluorine, silicon, aluminum, potassium and iron, all component parts of tourmaline. Under the microscope the capel shows a felted mass of minute crystals imbedded in a mass of quartz. In places you observe spots and patches where the quartz predominates. Some of these spots are oval and rounded, others angular, and a few that are naturally hexagonal in sections, naturally suggest the former presence of feldspar.

The rock forming the lode presents a similar mottled mass of fine needles in a ground mass of quartz, with granules of cassiterite in strings or veins. The needle-like crystals are very like some larger ones in specimens of undoubted schorl rock previously examined. The microscopical evidence is in favor of the opinion forced on Mr. LeNeve by the blow-pipe reactions, which is thoroughly in accordance with the views so ably brought forward 36 years

ago by Prof. Daubree with reference to the mineral association with tin ore.

The S. F. Microscopical Society.

The Seventh Annual Reception of the San Francisco Microscopical Society, was held Friday evening, Dec. 19th, at Mercantile Library Hall. Owing to the inclement weather a number of the exhibitors who reside outside of the city were unable to be present. The attendance, however, was good. The members of the society exhibited the various subjects upon tables arranged around the room. Many of the subjects were very interesting and were particularly well displayed under the costly and beautiful instruments. A list of the exhibitors present and the subjects assigned them is herewith presented:

William Ashburner, diatoms from Santa Monica, diatoms from Nijohing, Jutland, Denmark, diatoms from Richmond, Virginia.

Charles W. Banks, section leaf of water lily (*Nymphaea odorata*) doubly stained, section of wotlet of date palm (*Phoenix dactylifera*) double

Small Steam Yachts and Licenses.

Small steam pleasure vessels, or yachts, even when no larger than a pilot's yawl, under the present law have to pay annually as much in fees for license and inspection as a trading vessel of 100 tons. Even such an official as the Supervising Inspector-General of steam vessels sees this absurdity and injustice of this, and in his annual report calls attention to the fact and acknowledges that the excessive tax has in many cases actually prohibited the use of such craft. He recommends that the tax be made \$5, which he thinks will lead to the building of such vessels, and thus benefit a great industrial interest.

In our opinion, this, in itself, will lead to no very perceptible increase in the number of such small steam craft, though the recommendation is a very sensible one. What is really needed, is the abandonment of the absurd rule requiring a licensed engineer and licensed pilot (which officers must be represented by different individuals) on any steam vessels, no matter how small. It will be seen at once that an enforcement of this rule prevents the building of small pleasure yachts.

There does not seem to be any reason, so far as we can see, why a citizen of this enlightened and progressive republic shouldn't blow himself up as often as he chooses without having to pay a licensed individual to do it for him. As long as he does not carry passengers for hire, and only risks his own life and that of a friend or two, we can't see why the Government should step in and prevent him. The Government does not have any rule against driving a fast horse in a spider-web buggy; nor does it prevent oversparring a sailing yacht or vessel, or tell how big the sails must be.

But when steam is to be used the Government steps in and says the boiler shall be made so and so; a certain number of pounds of steam may be carried and no more; an engineer licensed only after examination by U. S. officers; and a pilot licensed only after examination by U. S. officers, shall be on board, otherwise you can't have a steamboat, and you must hush up or run aground only according to rules laid down rigidly.

Seriously, why shouldn't a man have a steam-boat for his own pleasure, the engine of which he can run himself if he chooses, provided he does not use the boat to carry passengers for hire. The licensed engineer and pilot are personages whose salaries alone far exceed all other expenses of a small steam yacht, for occasional use. Yet they are imposed upon the owner by law, and he cannot use his boat without them.

The consequence is that comparatively few small pleasure steamers are built or used. Very small ones, like little launches, are sometimes overlooked in the matter of engineer and pilot, but a boat 30 or 35 feet long is always "inspected" and fees paid. It would seem that after the Government safety valve—locked—is put on, no further interference on the part of U. S. officials is needed.

NOTES FROM TUCSON.—Our correspondent in Arizona, W. H. Seaman, sends us the following notes of interest from Tucson: The country is rapidly filling up with strangers, drawn hither by the reports of the richness of our mines. Several important mining properties have recently changed hands. Among the purchasers I notice Tom Farish and the Hon. J. K. Luttrell of California. Mark McDonald is now here examining mines. I have just come in from the new mining district called the Empire, on the northeast end of the Santa Ritas. Mines are now being opened there which will soon make a stir. The weather is delightful; cool nights and bright, sunny days.

THE town of Red Rock, Pa., in the oil regions, was recently almost consumed by fire. Three hundred families were burnt out and are rendered destitute. The loss of property will amount to \$200,000. During the burning the fire communicated with a 25,000 barrel oil tank. Rivers of oil flowed down Valley and through Main streets of Red Rock, burning all the business and private houses in the town.

THE appraisers of the estate of the late W. S. O'Brien place its value at \$9,655,459.37.

REPRESENTATIVE POUND will introduce, at the earliest opportunity, a joint resolution proposing a Constitutional amendment making the Presidential term six years, with no second term, and the Congressional term three years.

GEN. GRANT says he has not yet accepted the Presidency of the Nicaraguan Canal Company.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Salt Marsh Reclamation.

EDITORS PRESS:—Having been invited to visit the reclamation works of the Novato salt marshes, comprising nearly 5,000 acres, we went thither and spent two days investigating the whole area, with its systems of levees, flood-gates, ditches, irrigating canals, etc., and think the whole scheme of sufficient interest to be made the subject of a communication to your valuable paper.

The Novato meadows, as they are called to-day, lie about 11 miles north of San Rafael, in Marin county. The owner of these meadows is John W. Ferris, Esq., a civil engineer but, recently from England, but who has already earned a well-deserved reputation for skill, through the successful reclamation of Roberts island, near Stockton. This island has an area of 60,000 acres, and is to-day entirely under cultivation.

The reclamation works of the Novato meadows have been very intelligently planned by Mr. Ferris, and carried out with skill and economy by Mr. J. B. Christensen, assistant engineer, to whom the whole work has been entrusted.

The levees are 23 feet wide at base, 9 feet at top and 5 feet high. They are built with the compact salt-marsh soil, which renders them liable to ugly cracks in the dry summer months; but Mr. Christensen has had the happy idea to harrow them over several times, until the soil was thoroughly pulverized, and to-day not a single crack has manifested itself. This is a real improvement in levee building.

Twelve hundred acres have been plowed and immediately rented to eager tenants. The first crops on properly reclaimed salt-marsh land are very heavy and of excellent quality. Ladd's Sonoma meadows produced barley, bringing 10% more at the breweries than the good common brewers' market barley.

We really wish that our California capitalists would invest some money in the development of the real resources of California, instead of following so closely the narrow arts of the money lender. A. V. D. N.

San Francisco.

Machine for Harvesting Cane.

EDITORS PRESS:—There have been several pieces in the papers lately in regard to raising sugar cane; but it can never be very profitable in this State until some means other than by hand are devised to do the harvesting. To attain that end I propose to make an assignment (for nothing, to any one who will complete it) of all my right to a contrivance that will serve that purpose, which I have not the money or time to perfect. A model of this invention may be seen in your Patent Agency Office, and some of your readers may remember seeing a notice of it a little over a year ago.

JOHN HOWELL.

Anderson, Shasta Co., Cal.

Mines in the East.

The New York *Mining Record* of recent date has the following sensible remarks about placing mining property in the East:

We fancy that there is very much more difficulty in gulling the people, here in the East, into investments in worthless mining enterprises, than some of our contemporaries of the mining districts of the country seem to suppose. Here and there, occasionally, persons may be found so credulous as to make a purchase of a hundred shares in some worthless scheme; but, as a rule, there is exceeding difficulty in getting people to adventure their money, at times, even in really good mines, upon the most favorable reports of highly esteemed mining experts. Our city is being actively exploited, we know, by mine owners, but for one successful sale of a property, there may be counted more than fifty failures, including very many mines having the highest testimonials to their intrinsic worth. In very few cases can capitalists be found willing to take hold, single-handed, even of a mine of thoroughly demonstrated value. Such mines are generally placed by subscriptions taken by hundreds of individuals. We think the practical plan for any one having a mining property of genuine worth, is to have it examined and reported upon by some mining engineer of unquestionably good reputation, explicitly as to the precise extent and character of the work done in developing the property; the precise nature of the mineral resources visible and known to exist, with such details of elements of prospective profit as any reputable expert would venture to authenticate with his signature. Any effort to sell or place a mine in the East with less satisfactory evidence than this, is destined to end in utter failure.

Meanwhile, our contemporaries in the mining region, particularly in Colorado, may do good service by promptly exposing the facts about any mining claim which they may know to be falsely represented here in the East.

Metallurgical Processes in Montana.

The New York *Tribune* some time ago, sent Mr. Z. L. White through the mines of Colorado, the Black Hills, Montana and Utah. Mr. White's description of the processes employed by a company in Montana is so clear and comprehensive as to the methods employed for treating silver-bearing ores, that we deem it worthy of publication. Mr. W. says: "I may premise that smelting ores, which need only to be desulphurized in a reverberatory furnace, and milling ores, that need only to be desulphurized and chloridized are not to be put through the 'Krom' mill; all others are to be treated by the process I am about to describe. The ore, which, as it comes from the mine, is mixed with rock or gangue, is first put into a rock-breaker similar to those used in all quartz mills and for breaking stones for paving streets, and, after being broken into small pieces, falls into an inclined drying shaft, in which the moisture which it contains is removed. From this it is discharged upon a set of steel-rimmed 'Krom' rolls, between which it is crushed into pieces from one-fiftieth to one-tenth of an inch square. From the rolls the ore falls into a revolving screen, by which it is separated into two sizes; that which is already crushed fine enough is taken to the top of the mill by means of an automatic elevator like that used for loading and unloading grain, and that which is too coarse is taken by similar means to the next floor above, where it is delivered upon another set of rolls set closer together, and after passing through them is also taken to the top of the mill by an elevator.

"The ore is then separated into four different sizes by passing through a series of revolving screens, and each size is delivered in a separate bin. The next step in the process is the concentration of the ore—that is, the separation of the ore from the gangue or waste rock. This is accomplished by means of a simple machine, similar in the principle of its construction to a middlings purifier, used in the improved methods of manufacturing flour. As the rock, which is now of the consistency of fine gravel, falls from the bin which contains it into the concentrator, it is fed upon a fine wire network, through which a strong blast of air is forced in puffs following each other in quick succession. This blows the whole mass a short distance into the air, but the gangue, being much lighter than the ore, goes a longer distance and falls in a heap by itself, while the ore falls into a receptacle provided for it. The advantage of this concentration is that the bulk of the rock subsequently to be treated in the smelter, the battery, or the amalgamating or leaching-pan is reduced, often as much as 50% or 75%, and the cost of handling it thereafter is correspondingly less.

"After passing through the first concentrator the gangue has been in great measure removed, but the different classes of ore are all together. Some of it, containing 20% and upward of lead, is best treated by smelting; that containing less than 20% of lead or averaging not more than 5% or 10% may be amalgamated, and that carrying less than 5% of lead, leached. It is desirable, therefore, to separate the ore into three grades according to the proportion of lead which it contains, and this is done by means of other concentrators like that I have already described.

"The greater the proportion of lead which an ore contains the heavier it is, and the machines are so regulated as to deliver the smelting ores separately from those that are to be leached or amalgamated, and the last two classes are afterward separated from each other in the same manner. The working of the concentrators, of course, causes great clouds of dust, but above each is placed a hood connected with an exhaust-fan, which collects the dust and delivers it in a dust-room to be amalgamated or leached. The whole process I have thus far described is automatic; the ore passes from one machine to another without the intervention of workmen from the time the large pieces of rock are fed into the breaker until it has been concentrated and separated. At different stages in the process, the ores are weighed, and a record of them is carefully kept.

"Let us now follow the smelting ores. These are taken in cars to the reverberatory furnaces, where they are desulphurized simply by heating. They are then mixed with iron ores that have also been desulphurized in the same manner, and which are added to form a flux which shall carry off the gangue that may remain mixed with the ore. This is then melted in an ordinary 'water-jacket' smelting furnace, with coke or charcoal. The lead and silver, being heavier, sinks to the bottom; is collected in a small reservoir on the outside provided for that purpose, from which it is dipped and cast into bars of base bullion. The flux, consisting of iron and melted rock, is drawn off through an opening in the side of the furnace above the melted bullion. The base bullion may be refined, that is, the lead separated from the silver, either at the works where it is produced, or in the East where it is sold.

"Ores that are to be amalgamated, that is, those which contain from 5% to 10% of lead on an average, are first taken to a stamp mill, where they are reduced to fine dust in a battery similar to that used for reducing gold ore, except that no water flows through the battery. It is then placed in a 'Bruckner' cylinder, an immense iron cylinder six feet in diameter and twelve feet long, through which a flue passes,

which, connected with a furnace, heats the contents of the cylinder. This is then caused to revolve slowly, and the heat separates the sulphur from the ore. After this, common salt equal in amount to about 6% of the contents of the cylinder is added, the heat increased, and the silver which the ore contains is thus chloridized. This silver which the ore contains is now in such a condition that it has a strong affinity for quicksilver, and the pulp, agitated in an amalgamating pan with mercury and water, gives up its silver, which is collected in the form of amalgam on the bottom. The silver is afterward separated from the mercury by simply retorting it.

"The leaching ores, that is those which contain less than 5% of lead, are crushed in the stamp-mill, desulphurized and chloridized in the 'Bruckner' cylinders exactly as the amalgamating ores are. Then, after being cooled, they are placed in an agitator with a hot saturated solution of common salt in water, which takes up and holds in suspension the chloride of silver which the ore contains. The liquid is then drained from the pulp, and the chloride of silver is precipitated upon strips of copper, over which it is made to pass. The chloride of copper which the brine takes up is afterward precipitated upon iron and the solution of salt is used again. Finally the chlorine is separated from the metallic silver by means of heat. This is known as the 'Augustine leaching process.'

"From this brief description it will be seen that the process of reducing the refractory ores of Montana is a very complicated one, requiring skill and expensive machinery. If the owner of a mine yielding galena ore erects a smelter on his property like the smelters in which the Leadville ore are treated, he must add reverberatory furnaces, and even then can extract only a part of the silver which his rock contains. If he builds a stamp-mill and attempts to save the metal by amalgamation, he must chloridize his ore by the use of 'Bruckner' cylinders or some other similar machinery, and even then will fail to save all his silver. But when all the processes are combined and worked intelligently and economically, the most satisfactory results are attained."

Re-working an Old Mine.

The *Butte County Register* has the following to say about the old Banner mine: This mine, situated about six miles from Oroville near Oregon gulch, after laying idle for 20 years has again been put in working order, and the first clean-up has shown that the mine has not gone back on its former reputation, the clean-up for the first five days' work amounting to \$3,500. The history of this mine dates back to the flush days of mining in California, 1850. It was located by a company at that time and prospected to a limited extent and purchased from the original locators in 1852 by Messrs. Smith & Sparks, of Oroville. A shaft was sunk in 1853. While sinking the shaft the rock taken out was crushed by a spring pole mortar, wheeled to French ravine a short distance off and washed out, yielding \$500. The prospect was so encouraging that four arastras were constructed and worked by horses for about a year, when a 12-stamp mill was built and run by water during 1854. The water supply giving out in the early part of 1855, four arastras worked by steam were substituted. In the meantime a tunnel was being run to tap the ledge at a greater depth. The tunnel was finished in 1856, and a 12-stamp steam mill erected and worked continuously until 1859, yielding during the time it was worked \$600,000, when, owing to the lack of care in timbering the drift, a cave took place, burying two men whose remains were found upon the re-opening of the mine some months since after remaining buried for just 20 years. The extent of the original Banner mine was 3,300 feet. Extensions upon the ledge were located during the working, called the Southern extension and the California. These, with the Amoskeag and Coffee & Clark, two parallel ledges, making three which were located and afterwards consolidated with the Banner and a patent obtained under the name of the Minerva mining company. Arastras were put to work in the California ledge in 1855, and a thousand tons of rock crushed, yielding \$27,000. While a large amount of money was taken out of the Banner mine, the little knowledge possessed at that time about working quartz mines, labor at \$8 per day; lumber \$125 per thousand feet; nails \$25 per keg, and the extravagant habits of the times found the owners, when the cave took place, without means to re-open the mine. It subsequently passed into the hands of Joseph Trench, of San Francisco, and was held by him until about a year ago, when he entered into a contract with Kearney and Taylor, of San Francisco, to re-open the original Banner mine 3,300 feet and put everything in working order for one-half the property. The clean-up last week shows not only that they have filled their contract, but that they have got a valuable piece of property. About the time of the death of Mr. Trench, which took place a short time ago, Mr. Smith, one of the former owners, re-purchased Mr. Trench's interest, which makes him the owner of one-half the Banner proper, and sole owner of the extensions, the California and the Coffee & Clark ledges, for the opening of which, we are pleased to learn, Mr. Smith has secured all the necessary capital. The opening of these mines must, in the ordinary course of business, contribute largely to the support of Oroville, and be the means of attracting capital to other mines in the county.

The Old Inyo Mines Coming to the Front Again.

After a lapse of many years some of the oldest mining camps in Inyo county are beginning to show signs of returning animation. In a late number of the *Independent* we notice that considerable quantities of the precious metals are being extracted from regions long since abandoned and considered worthless. We notice, for instance the old Coso mines, situate westerly from Darwin some nine or ten miles, and long since supposed to have been worked out, has again donned the garb of activity, and where but a few years ago a few ragged Mexicans eked out a scanty subsistence with a small arastra or two, there are now fourteen in full running order, and all producing gold. This is one of the first camps established in the county, and as early as 1861 was worked, but when the Indian troubles began the miners were forced to leave. Some fabulous stories have been told to the writer hereof of rich gold quartz float having been found in the foothills of the old Coso range, many of which were doubtless true. The country has never been thoroughly prospected by white men; in fact, it is not an easy place to prospect in, as water is very scarce and difficult to find. Beveridge district is situate in the White mountains southeasterly from Independence. Although but a newly discovered district, Beveridge is also yielding up her quota of wealth. A few Mexicans with five small arastras are taking out as high as \$1,200 per week. Besides these Messrs. Porter, Hunter & Co., the original discoverers, have erected substantial works which are paying well. Then the old mines worked by McMurray & Co., years ago, have been put again in working condition by John Kelley, Chas. Schuman and others, and are now paying largely. Billy Lake, who opened the first stock of goods in Pine City, has a ledge which is said to be very rich. The Hitchcock boys have also a good paying gold lead, and there are many others which, if but thoroughly prospected, could be made to pay well. These are but a few of the many that could be mentioned. The rich silver, lead mines and gold leads of Cerro Gordo, and the later rich finds near Swansea, in fact the whole country to the east and south of Big Pine and Independence, presents a field for the industrious prospector and miner that cannot be surpassed on the western slope of the Sierras. The climate cannot be excelled. Water and wood in most places are abundant, plenty of fruit in season and the necessities of life for both man and beast can be obtained at little cost. The only one thing needful now is pluck and energy on the part of the prospector and miner, and the assistance of the generous inhabitants of the valleys, to make Owen's River valley one of the richest garden spots of the Sierras.—*Mammoth Herald*.

The Ivanpah Mines.

The new developments in these mines and the new impetus given to the work by the recent organization of the Consolidated Company, is attracting attention in mining circles, and in stock reports they are very favorably considered. Among the stock notes of one of the city dailies, we find the following:

Among new dividend propositions of the outside which will be listed at the San Francisco Board, is the Ivanpah Con. mine, one of the most meritorious properties in southern California. This mine is located on Alaska hill, Clarke's mining district, county of San Bernardino. It is only 11 miles from the boundary line of the State of Nevada, and about five miles from the company's mill and the custom mill. The Ivanpah mine is well situated for working purposes, and can be developed to the depth of 400 to 500 feet by tunnels running on the ledge. The old workings show a well-defined fissure ledge in dolomite limestone from east to west to the extent of at least 2,500 feet. The greatest depth hitherto attained is about 250 feet, and, although the mine has been worked from nearly one end to the other, in no instance has the ledge shown any signs of giving out. On the contrary, it is more clearly defined in the lower levels. There are, commencing at the west end, 10 chutes of ore, and toward the eastern end a continuous chute of about 300 feet. Thus far, however, only surface work has been done, and it remains to be seen what additional depth will disclose. The superintendent is now sinking a shaft from an old tunnel which is about 75 feet from the surface. The shaft is down about 60 feet, or from the surface 135 feet. The ledge is found to increase in size and richness at the bottom. The ore taken from this shaft is divided into two classes. The first class ore milled at the company's mill \$1,110 per ton, and the second class ore milled \$340.50. There are two railroad tunnels, besides several smaller ones, showing over 200 feet of stopping ground. The water right belonging to the Ivanpah mill is the best in the camp, and the road from the mine to the mill is good. Robert Sherwood and other capitalists of this city have sought a controlling interest in this valuable property, and under their energetic management we expect it to soon take its place among the reliable dividend-paying stocks listed at the board.

Mr. Will A. McFarlane has charge of the company's work, and has gone to Ivanpah to commence active operations, putting in new machinery and preparing for a vigorous prosecution of the work of getting out the precious metals.—*San Bernardino Index*.

MECHANICAL PROGRESS.

Quantity of Heat Utilized in the Steam Engine.

At a recent meeting of an Association of Engineers, in Liverpool, England, Mr. Emerson Bainbridge read an interesting paper on the details of an experiment made to ascertain the causes of the difference between the quantity of heat in fuel and the quantity which is utilized in the work done by a steam engine. He said that the most economical mode of producing and using steam power formed a question of special interest at the present day for engineers, this leading to the problem as to the scope that might exist for the utilization of the large margin of loss in the difference between the heat contained by the fuel and the small percentage of such heat which is represented by the work actually performed by a steam engine. Only 11% of the actual heat power contained in the fuel was utilized, and though a large proportion of that loss could never be overcome, the importance of the inquiry was evidenced by the fact that every 1% gained, means in the consumption of this country alone, a saving of about half a million tons per annum. About 50,000,000 tons were annually used in the production of steam, which was about 37% of the whole output.

The coal used in dwellings, great as was the waste, was more fully utilized than when it was used in any other way, thus 13% of the heat actually possessed by fuel was given off in an open fire-place. As an instance of the small amount of heat utilized, it was stated that to produce three pounds of steel seven pounds of coal were required. The author then gave the results of an experiment he had made with the winding engine and boilers of a small colliery, such plan being nearly 30 years old. Some of the improvements which might be made with a view to promoting economy of fuel, were the fixing of boilers of an improved construction with a minimum thickness of plates and a maximum area of heating surface. Special attention should be paid to the manner in which air is admitted to the fire, and to the working of the damper. The air intermingled in the fire-grate should be so intermingled with the gases from the fire as to enable a minimum quantity of air to be used. The application of such form of fire-grates and such mode of firing as will enable the cheapest quality of fuel to be used; the complete covering of all exposed hot surfaces; where water is scarce the application of the best form of water heater; where water is plentiful the adoption of an improved form of condenser; steam jacketing of the cylinder, and mechanical accuracy in the construction of the engine; the application of the system of variable expansion when the work done by the engine varies; in case of winding engines, the adoption of drums of varying diameters; as a general principle, the use of steam at a high temperature in order to have the greatest possible difference in temperature between the steam when it reaches the cylinder and when it has done its work.

In the application of such improvements to ordinary steam engines, the saving in working cost must, of course, first be considered, and in the adoption of all such means of promoting economy, as have been alluded to, it may be confidently asserted that the saving in working cost will, as a rule, wipe off the extra first cost incurred in a very short time, since the saving effected will probably vary from 50% to 150% per annum on the first cost.

Auxiliary Governor for Engines.

A new governor has been invented by Mr. John Milton, of Hamilton, Va., which consists in arranging a lever, or other movable device, in such relation to the main or driving belt of the engine that, when the slack of the belt is taken up by the reason of the increased tension thereon (due to an increased load being thrown on the engine), said lever or device will be depressed or changed in position, which will (through suitable connecting mechanism) raise a valve located in the steam passage, and thereby open the latter and allow freer admission of steam to the engine, so as to instantly increase the power of the latter and prevent diminution of speed.

The operation of the auxiliary governor is as follows: When the engine is running without much change in the load or draft, the ordinary governor controls its action by regulating the admission of steam; but if the load is considerably and suddenly increased, the engine will be at once slackened, because the ordinary governor will not act quickly enough to instantly open the valve and thus allow admission of the full head of steam to the piston-cylinder, for the purpose of counteracting or opposing the tendency to retardation of velocity. This function is performed by the auxiliary governor in the following manner: When the increased load is thrown on the engine, the rotation of the power shaft is diminished proportionately, so that the lower half of the belt will be thereby suddenly subjected to increased tension and drawn taut, while the other half will be simultaneously slackened. The short arm of the lever is thus depressed and its weighted end raised, and this arm attached to its fulcrum thrown over to the left, so that the pinion or rock shaft is rotated a part of a revolution, and the valve thereby

raised from its seat. This movement of this valve opens the branch and allows free admission of steam to the steam-chest. The increased pressure of steam in the cylinder instantly adds to the power, and tends to accelerate the speed of the engine. This occurring coincidentally with the application of the increased load, this tendency to retardation of velocity is overcome, and hence the speed of the engine is maintained undiminished.

It is obvious the sensitiveness of the auxiliary governor may be increased or diminished by shifting the weight along the lever, since this will increase or diminish the pressures of the friction roller on the belt, and thus cause an increased tension of the latter to vibrate the lever—that is, affect its position more or less quickly.

Steel Castings for Machinery.

Among the engineering exhibits at the late International Agricultural exhibition at Kilburn, England, one of the most interesting allusions to the metallurgist and the machinist, was a collection of steel castings produced at Newburn-on-Tyne by Messrs. John Spencer & Sons. As illustrative of the various applications of steel to the purposes of machinery, this extensive collection was most instructive, especially at the present time, when steel is daily asserting its claim to be considered "the metal of the future," and when the demand is increasing for machinery at once light and strong, and capable of resisting a great amount of wear and tear. The articles exhibited by Messrs. Spencer were of the most varied form and application, including spur-wheels, pinions and geared wheels of all kinds, rings of gear and winding drums for traction and for steam plows, wheels and sheaves for collieries, mines, etc., solid-disc railway wagon wheels, crank-axes, brackets, rollers, clutches, axle-boxes, hydraulic cylinders, together with a great variety of engineering castings, projectiles etc., these specimens shown varying in weight from 10 lbs. to 30 cwt. each. All the castings displayed remarkable soundness, those made from steel of the milder qualities possessing a very great degree of toughness, some of the test pieces being capable of bearing a tensile strain of 30 tons per square inch, with an elongation of 25% before fracture. Such a material is well suited for any work having to withstand sudden strains, or where a high degree of ductility is required. The harder qualities which stand a tensile strain of from 40 to 50 tons per square inch, with an elongation varying proportionately from 15% to 3%, are applicable to various uses, according as greater resistance to abrasion, or more or less ductility is required. It is the remarkable capability that steel possesses of being thus varied in hardness and toughness, which constitutes the immense value of that metal for the purposes of the engineer and machinist, and which has already caused it to displace cast-iron in so many constructions. Messrs. Spencer's exhibit served in an admirable manner to demonstrate the capabilities of cast-steel, and promises well for the future development of this important branch of manufacture.

The Transmission of Power by Belting.

The results of an extensive series of experiments on belts and belting have been published in France by M. Leloutre, in the Transactions of the Societe des Ingenieurs Civils. The subjects examined were the elongation, elasticity and breaking strain of driving belts made of leather, india-rubber, webbing and canvas; and the slipping of belts and cords. Some practical applications made of these results in the transmission of power by belts, are also given.

The experiments on elongation, elasticity and breaking strain were made by cutting from any leather belt, or from the hide, a strip about 30 inches long and two to two and a half inches wide, which was further subdivided into three or four narrower thongs, for testing in different ways. Two fine lines were marked across the thong, at a distance of 20 inches apart; and the width and thickness of the thong were carefully measured at several intervening places, to determine the corresponding transversal sectional areas, the minimum of which was taken for calculating the strains. Any probable errors involved in the results so arrived at did not exceed two per cent.

The general results of the experiments on leather, india-rubber, webbing and canvas are that the elongation produced by a tensile strain is in no respect proportional to that strain, but increases always less rapidly than the tension; in other words, the modulus of elasticity for these materials rises higher and higher as the load increases, while for metals it falls lower and lower. One curious fact, however, which the experiments disclose is that, while the elongations or successive increments of length become less and less up to a certain load, they then become greater and greater, showing a point of maximum power of resistance, which is then followed by a falling off; after this decline of resistance, the elongation again becomes less rapid up to this breaking strain, on approaching which the resistance is generally greater. In ordinary leather the maximum resistance to stretching is met with at a strain of about 850 pounds per square inch; in india-rubber and webbing it occurs at rather a lower strain. It is evidently advantageous, therefore, that the working strain on a belt should be fixed as near as possible to that at which the maximum resistance to stretching occurs, or say from 700 to

800 pounds per square inch. This is largely in excess of the tension generally recommended of 200 to 300 pounds per square inch, which itself is even regarded with timidity by many engineers. Should the point of maximum resistance to stretching be accidentally exceeded by the strain in working, no trouble will be experienced. This is owing to the fact, demonstrated by experiment, that the elasticity of leather and webbing is perfect; for when things have already been twice torn asunder, the severed shreds, after having been stretched one and a half inch per foot, have been found with fifteen months' rest to recover exactly their original length.

AUTOMATIC FIRE LIGHTER.—A novel device for lighting fires automatically at any prescribed time has recently been patented by Mr. E. H. Dorchler, of Homestead, Iowa. It is intended for the use of housekeepers, country school teachers, manufacturers, and others, who require a fire at a stated time. When this device is used personal presence is not required; all that is necessary is to prepare the kindlings and fuel beforehand and set the apparatus. The mechanism is controlled by a clock, upon the hour hand arbor of which there is an adjustable disk similar to that of an alarm clock, which carries an arm capable of engaging pins projecting from the periphery of the wheel, which carries seven pins corresponding with the seven days of the week, and arranged so that they may disengage a pawl from the ratchet wheel at any prescribed time in the day. The ratchet is upon the shaft of a small windlass that is propelled by a weight when the pawl releases the ratchet wheel. This windlass winds a cord that may be extended in any direction to the stove or furnace where there is a lighter, consisting of a horizontal wheel, around the periphery of which is wound the cord from the windlass, and upon the upper surface of which there is a coating of sand or sand paper. The wheel is protected by an iron cover, which also supports a clamp for holding one or more matches, so that they press lightly upon the sanded surface. A piece of paper or other combustible material extends from the match to the kindlings in the fireplace. The operation of this apparatus is obvious. At the prescribed time the pawl is released, the weight drops, the sanded wheel revolves, and the fire is lighted. If it is desired to skip a day or so, the pins in the wheel, which represent the days to be skipped, are removed.

SCIENTIFIC PROGRESS.

Proposed Method for Dissociation of Metalloids.

Much thought has of late been given by chemists and physicists to the possibility of decomposition of the substances that have been called elementary. Some phenomena of solar spectroscopy, taken along with the fact that solar temperatures are vastly higher than any realizable in the laboratory, seem to indicate that our ideas of the so-called elements may require considerable modification. There is reason to think that the metalloids, with the exception, perhaps, of oxygen, are dissociated in the sun. The well-known physicist, M. Raoul Pictet, has been pondering the possibility of dissociating them experimentally and by means of solar radiation. Guided by theoretical considerations (which are given fully in a recent number of the *Archives des Sciences*), he has proposed a method, which he thinks might prove successful; unfortunately, he is not in a position to realize it himself. The method is briefly as follows:

The sun's rays should be concentrated by a large parabolic mirror of silvered copper with about 10 meters' aperture; the weight need not exceed a ton and a half, and the mirror should be mounted so as to follow the sun's course. The total radiation would converge on a circular surface about 8 to 10 centimeters in diameter, giving about 1,000 calories a minute. Here M. Pictet would provide a "solar chamber" to receive the metalloids to be acted on by the concentrated heat which would be available after loss by radiation and conduction through the support. The solar chamber should be of nearly spherical shape, hollow and about one meter in diameter; one-half, directed to the sun, being of zirconium or lime (the most resistant substance known); the other half, directed towards the interior of the mirror, of hard glass, with curvature calculated to favor the passages of the solar rays converging to the center of the chamber. The zirconium or lime should be heated exteriorly by an oxyhydrogen blowpipe, to diminish the loss of heat by radiation. Through a zirconium tube in the top of the chamber, vapors of the metalloids (chlorine, sulphur, bromine, iodine etc.) should, by force of suction, be made to pass downwards through the zone of maximum temperature; and here a dissociation might be hoped for. One of the new vapors formed would pretty certainly diffuse into the surrounding space more rapidly than another. To fix this element and keep it from recombination, M. Pictet, would provide, in the lower part of the chamber, a wide metallic tube with a cooling envelope of liquid sulphurous acid, and a series of pieces of metallic netting with fine meshes, through which the vapors of the chamber should

be drawn off. By exact analysis before and after insulation, new elements might be looked for. It is, of course, impossible to say in what state they might be condensed or crystallized; but in any case, by continuing the experiment some time, enough of the substance might be collected to allow of its properties being studied.

STEAM JET SIGNALS.—Considerable attention is being drawn to the utilization of the steam jet as a medium for conveying signals to a great distance. It is well known that when a strong ray of light is thrown upon a jet of steam issuing forth into the darkness, the steam becomes brilliantly illuminated, and the light thus transmitted is visible from long distances. The example of this, frequently seen in steam issuing from a locomotive engine at night, when the driver opens his fire door, has not been lost, for, taking advantage of this principle, M. Carl Otto Ramstedt, late of the Russian navy, has devised a system of night signaling on board ship, with which some experiments have recently been made by the Trinity Board. The apparatus consists of a dish chamber, in which the inventor burns strontium or other substances so as to produce a variety of colors if desired. At the back of the chamber is a reflector, by means of which the light is thrown on the steam either steadily or in flashes at will. The steam thus becomes a luminous mass, varying in color with the substances used in combustion. The result of the experiments recently made showed it to be very effective and applicable to its intended purpose, and there appears to be little doubt that it will prove of value as a means of signaling at sea.

CHEMICALS THE MEASURE OF COMMERCIAL PROSPERITY.

Prof. Roscoe, in a late lecture on technical chemistry, remarked that the commercial prosperity of a country may with great accuracy be estimated by the amount of sulphuric acid it consumes. This will readily be acknowledged as true when it is borne in mind that there is scarcely an important branch of industry which, directly or indirectly, does not need to employ sulphuric acid for carrying on some of its processes, and when you learn that the result of this universal demand is that no less than 850,000 tons of sulphuric acid were manufactured in Great Britain in the year 1875, whilst this enormous amount is likely steadily to increase. By far the largest portion of this acid is employed in the manufacture, from common salt, of the alkali soda in the different forms, the remainder serving to carry on an endless variety of trades, amongst which those of the artificial manure maker, the gold and silver refiner, the candle maker, the dyer and bleacher, the calico printer, lucifer-match maker, the wire drawer, the galvanizer, and the color maker may be mentioned as some of the more important.

ELECTRICITY.—A paper by Dr. Warren De La Rue and Dr. Hugo Müller, on the electric discharge with chloride of silver battery, 11,000 cells, was recently read at the Royal Society. The authors find that for all gases there is a minimum pressure which offers the least resistance to the passage of an electric discharge. After the minimum has been reached the resistance to a discharge rapidly increases as the pressure of the gas decreases. When the discharge occurs there is a sudden expansion of the gas, in addition to and distinct from that caused by heat. This expansion ceases instantaneously when the discharges cease. The appearances presented by the electric arc in air, hydrogen, carbonic acid, etc., are extremely beautiful. It is shown that the electric arc and the stratified discharge in vacuum tubes are modifications of the same phenomenon. These and other effects will be exhibited at the Royal Institution in the ensuing season by means of a new battery of 11,000 cells, which Dr. De La Rue is putting together.

ARTIFICIAL COLORING OF FLOWERS.—Professor Sarchado, of Padua, continues his interesting experiments of artificially coloring the corolla of flowers. There is nothing new in the plan, but the matters employed are original. He simply causes to drink certain colored solutions—aniline chiefly, which penetrating the tissues, modify color—in fact dye the nervelets and veins of the corolla. Gardeners are aware, that, by mixing iron filings with the soil around hortensias, the latter receive a blue tint. The roots of pansies and stocks, dipped in a solution of green aniline, become colored in their flowers in fifteen minutes. But the plant dies in the course of a week. Watering the soil with a colored solution does no good, as the earth absorbs the coloring material.

NEW THEORY OF TERRESTRIAL MAGNETISM. The theory lately advanced by Profs. Perry and Ayrton, of Japan, to account for the magnetism of the earth, and which has provoked much discussion, is thus briefly summarized in the *Philosophical Magazine*: They find this cause in the revolution of the earth beneath the electrical charge, originally, and at all times present in the atmosphere. They prove that "if the earth be electrified, it must, from its very rotation, quite independently of all other bodies in the universe, be magnetic; and if it consists of a shell of iron, thick or thin, then that the law of distribution of magnetism produced by this electrical charge in mechanical rotation, between it and space would be sufficient to produce the necessary amount of charge."

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals.

Mining Share Market.

The advent of Christmas brought no rise in the stock market, and the San Francisco Board adjourned over from Wednesday until Monday next, to give the market and the brokers "a rest." The rumor that J. C. Flood, of the Bonanza firm, the ruler of the stock market for several years, is to retire from mining stock-broking, is a topic of conversation among the "fraternity." It is said that John W. Mackay is also about to retire. The news does not seem to have produced any unusual depression, but rather on the contrary. The question is who will take up the reins in their stead, and control the Comstock.

Virginia City just now is in a serious state of depression, but as they have all seen such stock tumbles before, they ought to be used to it by this time.

The crash seems to be due more to a demoralization than to any very disastrous change in the mining situation. The radical change in the plan of operation of the Savage mine no doubt brought about the crash, as it must have upset many plans made by stock purchasers. As we go to press one day earlier than usual this week, to make a holiday of Christmas, we have been obliged to omit our usual summary of news from the Comstock mines.

The advent of Eastern investors into mining operations has not made itself manifest among us to any great extent. They do not seem to care much about dipping into our stocks but are rather looking out for mines, which they, strange to say, seem to want to work for what is in them. As long as this principle is held to, they are likely to do better than if investing at hap-hazard in any stock which is offered to them and which will be subject to the manipulations of some "insider."

The Homestake Mining Company of Dakota Territory have declared their twelfth consecutive monthly dividend of 30 cents per share, aggregating \$30,000, or \$360,000 in all, payable here and in New York on the 26th.

November's Bullion Yield.

The Bodie Con., Caledonia, Homestake, Idaho, Father de Smet, Original Amador, Plumas-Eureka, Sierra Buttes, Stewart (Utah), Murchie, Florida Hill and Black Jack (Idaho), gold mines, and the Silver King silver mine have neglected to make any return of their bullion yield for November. That of the gold mines was as follows, with the returns of Bodie Con., Caledonia, and Homestake estimated:

Bodie Con., \$75,000; Black Bear Quartz, \$14,900; Caledonia (Dakota), \$5,000; Excelsior Gravel, \$62,000; Golden Terra (Dakota), \$27,000; Homestake (Dakota), \$60,000; Idaho (Nevada county), \$20,000; Mammoth (Mono county), \$1,400 in silver, \$8,400; Milton Gravel, \$71,000; North Bloomfield, \$15,900; Oneida, \$7,300; Pittsburgh, \$4,400; Syndicate (Mono county), \$12,300; Standard Con., \$10,100 in silver, \$133,800. Total, 14 gold mines, \$517,000.

The yield of the silver mines was: Alexander, \$27,200; Belle Isle (Elko county), \$5,400 in gold, \$64,700; Christy (Utah), \$20,100; Day, net proceeds of ore sold, \$4,300; Extra, \$3,500 in gold, \$14,700; Hillside, \$45,000; Manhattan, \$155,500; Northern Belle, \$92,600; Navajo, \$7,800; Ontario (Utah), \$129,200; Paradise Valley, \$24,300; Raymond & Ely, for October, \$11,600; Silver King (Arizona) estimated \$25,000; Star, \$25,800; Stonewall Jackson (Arizona), \$13,700; Tiptop (Arizona), \$31,700; Vulcan (Mono county), \$14,200. Total 17 silver mines, \$707,400.

The mixed metal mines yielded as follows, the first sum being the gold, the second the silver and the third the total: California, \$69,500, \$56,300, \$125,800; Con. Virginia, \$108,000, \$90,400, \$198,400; Eureka Con., \$40,200, \$161,500, \$201,700; Ophir, \$41,200, \$61,700, \$102,900; Total of gold \$258,900; of silver, \$369,900; of both \$628,800. The silver total of Eureka Con., includes \$55,300 of lead. The total yield of gold of all mines for last month was \$773,300; of silver \$1,024,200, of lead, \$55,300. The yields for November, 1878, were, respectively, \$896,100, \$975,600 and \$20,800.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Belmont, Dec. 22d, \$4,393; Northern Belle, Dec. 15th, \$6,585.59; Bodie Con., Dec. 16th, \$50,200; Northern Belle, Dec. 17th, \$6,736.01; Bodie Con., Dec. 23d, \$11,691; Gold Hill (Idaho), Dec. 17th, \$33,288.

Rumor says that Congressman Cannon, of Utah, who is already under indictment for violation of the anti-polygamy law, has taken a fifth wife. Several bills are likely to be introduced into Congress against polygamy, and there will be much opposition to the admission of Utah as a State.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

EMPIRE.—Amador City Sentinel, Dec. 17: Mr. Matigomery, an experienced miner, has taken the position of Superintendent of the Empire mine, and Mr. W. T. Jones resumes his old place as foreman. Frank Paron, an Austrian miner in the Empire mine, was killed by a large rock falling upon him in the shaft which he was descending.

UTTER BASIN.—The water at the Butte Basin mine flows in as freely as ever, and though pumping is continued without intermission, it cannot be got under control. It is thought that the country for miles around will have to be drained before the search for the gravel can be continued.

CONEY.—Work on the Coney mill is being pushed rapidly. The sliding is now up, and shingling will be commenced in a few days. The roof is said to be the largest in the county. The building is 80 ft square. A large amount of machinery is already on the ground, and more is being received every day.

ZELIE.—Amador City Times, Dec. 19: Considerable heavy mining and mill machinery has arrived at the Zelle depot, and is being rapidly hauled to the Zelle mine by teams, and is being already started on the road. In the mine a track is being laid in the 1800 level, and preparations are being made for taking out ore. The mill building is rising rapidly. Graveling has also been commenced for the erection of a substantial residence. It is the intention of the owners to do all the work they possibly can around the mine and mill by machinery.

GOVERN.—Amador City Ledger, Dec. 20: The large volume of water that was struck some weeks back in the north drift, is now fully conquered. At first there was at least 40 miners' inches flowing into the shaft, which filled up the shaft a distance of 150 ft. At present the flow does not reach more than three or four inches, and this is under easy control. The work of extracting rock was resumed last week. The ore is of fair grade, and altogether the prospects of the mine are better than they have been for a year past. There are about 80 men on the pay roll of the company.

NORTH GOVERN.—The contract for running the tunnel will be completed this week, leaving the drift 125 ft from the North Govern line. Another contract will be let at once. At present no ledge appears in the end of the tunnel.

MARYLAND.—The new hoisting works are finished and running; the whistle blew for the first time on Thursday last week. A combination shaft has been started, by means of which it is proposed to operate both the Maryland and Seaton. A small ledge has been disclosed in the Maryland. There are from 25 to 30 men employed.

BUNKER HILL.—A clean-up was made at this mill last Monday, which yielded at the rate of \$10 per ton. The mine continues to look well.

BUTTE.

ORO MINER.—Oroville Mercury, Dec. 19: This property is located on South Fork, about three and a half miles from Enterprise. It is owned by the Oro mining company, a majority of the stock being held in this city. Work in the shaft was discontinued last season and tunneling began. The tunnel is now in a distance of 613 ft and 7 inches. Should the ledge not be struck in the distance expected (15 ft) the management will cease work on the tunnel and erect hoisting works over the shaft and sink it 200 ft deeper. The capital stock consists of 50,000 shares, \$2,700 of each being paid up. The shareholders, pro rata, at the value of six cents per share. San Francisco capitalists recently offered to purchase those unsold shares at 15 cents per share, but the stockholders refused to sanction such a transfer. Work on the tunnel is now progressing at the rate of three ft per week. All the work done has been paid for, and the company is out of debt and has cash in the treasury.

ARMSTRONG.—A five-stamp quartz mill is being erected on the Armstrong mine, which is located about three miles from Boston Ranch, on the La Porte road. San Francisco parties are managing the development of the mine, which is believed to be a valuable one. The rock assays very high.

CLOSED DOWN.—Work has ceased on the Bader mine, Dogtown district, for the present. The purchaser of the mine also closed down. Mr. Barrett is reported to have recently discovered surface croppings of what is likely to prove a bonanza.

CONTRA COSTA.

CINNABAR DISCOVERY.—Antioch Ledger, Dec. 20: For two years past parties have been engaged in tunneling a hill on the ranch of A. S. Howard, on Marsh creek, in search of a vein of cinabar. The tunnel is in about 150 ft and it is authoritatively reported that a vein two ft in thickness and well defined has been discovered during the past few days. Richard Matthews made the discovery, and thinks he has an excellent prospect. The croppings, extending about a mile from the beach ranch toward the Mount Diablo foothills, indicate a quicksilver vein.

CALAVERAS.

GOOD PROSPECT.—Angels Echo, Dec. 16: Some five or six years ago, Robert Sloan and Davis Ounby, while prospecting near Vallejo, discovered a large quartz ledge, running east and west. The vein averages about 15 ft in width and is of a light color. When first discovered the prospects were only fair, but it was not valued very highly by the owner, since which, however, they have prospected it more thoroughly, and it has proved to be a valuable claim. On two occasions they have had the rock tested, by what is known as the Willard process, one lot of which yielded \$40, and the other \$28 per ton. Mr. Ounby sold his half of the claim recently to a gentleman named Birch, who is a practical miner, and his partner, Mr. Sloan, and it is altogether probable that they will proceed to develop this immensely rich body of quartz.

DEEP BLUE.—The Deep Blue Gravel mining company will soon be ready for operations. Their mine, which is situated near the Monarch mine, and about four miles from Angels, has been thoroughly prospected and is without doubt one of the most gigantic operations in Calaveras county. W. A. Keefe, the Superintendent, is a practical business man and a good miner.

DOLAN.—The Dolan mine is looking well. The mill, which is a ten stamp one, is about completed; it is an excellent piece of work.

CAVED IN.—The tunnel which drains Vallejo flat, and which is known as the Cohen tunnel, caved in for a hundred ft, completely filling up and not valued very highly by the considerable damage. This will probably interfere to some extent with the working of the claims on the flat.

EL DORADO.

A NEW GOLDEN.—Cor. Democrat, Dec. 20: In a recent prospecting tour in the hills, near Kelsey, I found, on the top of one ridge, the largest quartz-carrying I ever saw. It extended over 60 ft from east to west, and more than 100 ft from north to south, one solid mass of big white quartz boulders. In the seams and honey-combs on the surface of the boulders I discovered innumerable specks and particles of pure gold, some as big as a pin-head, or larger. In one place the hanging wall had crumbled away, and had revealed a seam of gold about 12 ft in length of nearly vertical ledge exposed, and all over the surface of this I found fine particles of free gold liberally sprinkled. On another hill-top, not more than 200 yards from the one just described, I inspected another ledge about eight ft thick, and in a large number of pieces of quartz I broke off I found gold freely sprinkled. At one place in this ledge I found a seam of solid sulphurets, between three to four inches thick, with here and there particles of free gold projecting out of the sulphurets.

FRESNO.

NEW DISTRICT.—Fresno Examiner, Dec. 13: Among the miners of Coarse Gold gulch and vicinity a universal desire has been manifested on account of the long distance, expenses and inconvenience of going to Fresno to record mining claims, that a mining district be organized. Accordingly, at a recent meeting, the boundaries of a new district, to be known as the Potter Ridge, were mapped out, and suitable by-laws adopted therewith.

MARIPOSA.

THE VIRGINIA.—Mariposa Gazette, Dec. 14: The Virginia mine, about three miles from Coulterville, was located, in 1850, by a company of miners who supposed it to be a payable mine if well worked, but nothing extra. It passed from hand to hand until purchased by a Mr. Coe, of New York, a man of no experience in mining quartz. Johnson & Co. drew him into the purchase and thought they had secured a big fish. But they proved otherwise. For after he got into it he tested rock from all parts of the mine, aided by Lewis White, an old and experienced miner and one of the original locators. After fully satisfying himself that it was a good mine, he purchased all of the Hunter's Valley machinery and moved it over to the Virginia, and now has a first-class eight-stamp mill nearly completed. They are sinking a shaft about 100 ft, and a tunnel to connect the works. The tunnel is run on a level with the mill, and ore will be dumped at the batteries. In the shaft they have had splendid ore from the surface down, but now have exceedingly rich ore. The vein is two and a half ft thick. Mr. Coe will have sufficient ore to pay Jan. 1st to pay for his mine, mill and all other expenses, besides having a mine worth \$1,000,000.

BAWDER.—The Bawder mine is progressing rapidly with a fair vein and rich rock. Suitable mill will be built for this mine as soon as the spring opens.

BOWER CAVE.—The Bower Cave mine, situated on the North Fork of the Merced river, above Bower Cave, was sold by Dr. Austin to P. P. Mast, owner of the Banderita mine. A contract was let for running a tunnel 200 ft along the vein, which work is progressing rapidly with a fair vein and rich rock. Suitable mill will be built for this mine as soon as the spring opens.

BUNNELL.—The Bunnell mine, on Bull creek, was recently sold by Peter Longhurst to Brown & Loos, who will erect hoisting works on the mine immediately. Mr. Longhurst is repairing his mill, on Bull creek, to crush the ore for them.

NAPA.

PUEBLO QUICKSILVER MINE.—St. Helena Star, Dec. 20: The camp is keeping up its usual business, working 22 men and producing about 100 flasks a month. They are now using ore from the Washington mine. Mr. Patton is Superintendent. Freight is ten dollars a ton from here over in winter, and eight in summer.

DISCOVERED.—A manganese mine is reported discovered on Moore creek, near Conn valley.

PLACER.

DUTCH FLAT.—Fresno, Dec. 13: Our mining interests are assuming greater activity as the season advances, the abundant rains having furnished an amply supply of water for washing. The Polar Star and Southern Cross are both in active operation, employing between thirty and forty men each, and working two shifts. The Franklin claim is presently idle, but we are informed that the company intend soon to start a new tunnel at a lower level from Bear river, as the pay dirt is largely below the old tunnel, which is nearly useless, unless for working the top dirt. The Leckamp mine is working a small force, and so far, report a very successful run. A Larson has several men at work in the Shady Glen, with good prospects. The Central company are operating in new ground in a different portion of their claim from last season. The ground, it is said, prospects very fair.

RECU FLAT.—Placer Herald, Dec. 20: This flat, near Auburn, that was so rich in early days, is again the scene of some activity. The Wright Bros. are sinking on a quartz ledge that crosses the flat, with fair prospects. They have a ledge from 3 to 3 1/2 ft thick, on which they are down between 30 and 40 ft, and they find gold in the rock from the top to the bottom. On the same ledge, further east, Mr. Robert Stuart has also sunk over 20 ft. Where the latter is sinking, the ledge is at least 7 ft thick.

MONO.

BODIE DISTRICT.—News, Dec. 21: In the Jupiter a west crosscut has been started, which will be carried the entire width of the vein formation. The greater part of the pumping machinery is now on the ground, and the work of preparing the foundations, tanks and tank stations is being pushed rapidly forward. In the Bodie work it is being pressed as fast as hoisting facilities will permit, and as soon as the 400 level has been reached north and south, drifts on the ledge will be commenced, and east and west crosscuts will be driven the entire width of the ground. In the Dudley the sinking pump is moved up to the station, from whence they pump to the 300 level. The Bodie mine is rapidly growing in wealth and in good demand. The face is now in nearly 1,400 ft. A vein of fine quartz, of good milling quality, from 12 to 16 inches in width, was cut 1,375 ft from the mouth. In the Boston Con. the 200-ft station will be opened by Jan. 1st. It contains some very high-grade ore, assaying into the hundreds. Ore is being run to the new mill of the Noonday mine, which commenced crushing on Dec. 22nd. The Standard mill has started up again, and the manufacture of gold bricks goes on steadily. The Spaulding mill is near completion.

MAJORITY DISTRICT.—Herald, Dec. 17: Work on the H. L. & M. C. Joint tunnel is being pushed on rapidly. The drills have been kept working constantly since Dec. 1st. The ground is still a mixture of wash gravel and cement. The Mammoth mill resumed crushing last Sunday, with every prospect of a good output, and shares in good demand. The strike is reported in the Mammoth mine, the ledge being eight ft wide. The Superintendent of the Homer mine makes a favorable report, saying, in conclusion, that the miners are now all stockholders, and manifest great interest both in the progress of the work and the value of the ore obtained in driving ahead.

CLOVER DISTRICT.—Cloverton correspondent of the Mammoth Herald.—The Cloverton mines are the subject of speculation at present. The ledges are all large and the assays very good. In the Wild Rose assays range from \$140 to \$225. The Oro Fino, a ledge of over 40 ft in width, assays from \$40 to \$112 at a depth of only 27 ft. The Vulcan mill will start up in a few days for a long run. The ore sent in from the mine is unequaled by any heretofore found in the camp.

NEVADA.

MURCHIE MINE SULPHURET WORKS.—Herald, Dec. 20: The Murchie company has lately completed the new sulphuret works erected near the mill. Mr. Smith, in whose charge the works are, has, after several months of experimenting on a new chlorine process, brought it to a satisfactory issue, and the company has sold back last month sulphurets to enable him to give his new process a fair test.

CULBERTSON'S SAILOR FLAT MINE.—Transcript, Dec. 18: The tunnel for drifting is in about 400 ft. Prospecting is being carried on in the breast, in hopes of rediscovering the main ledge which was lost by a cave some two years ago. Very favorable indications have been found recently, and unless some substantial developments are made soon, hydraulic will be commenced.

MT. AUBURN.—Steam will be started up at Mt. Auburn's new hoisting works some time next week. The present workings are several hundred ft east of the old shaft.

SCOTT'S FLAT.—John Noyes, at Scott's Flat, is doing regular washing in his hydraulic claim, and will make the first cleanup for a dry hole about three ft deep was drilled. Marshall cut a cartridge in two, and placing one half in the hole, proceeded to push it to the bottom. As he got it pushed part way down, it ignited, probably by friction.

He stood directly over the charge, and the flames shot up into his face, blistering the flesh between the mouth and forehead. The swab-stick which he was using as a ramrod was forced out, and pierced his upper lip. In behalf of the Pattison powder, it is claimed that during the process of charging the hole with the powder, Mr. Marshall thoughtlessly used a swab-stick of one of the miners of the Merrifield mine. It is possible that a certain amount of ultra-glycerine, which is one of the ingredients that is contained in the powder used at this mine, had congregated at the end of the swab-stick, and that the friction of the latter against the Pattison powder was the cause of the accident.

SAN DIEGO.

JUANAS MINES.—San Diego Union, Dec. 18: Agents of parties interested in mining matters at San Francisco have been in Julian and vicinity nearly all summer, ostensibly as tourists and pleasure seekers, but really engaged in privately investigating two or more of the claims there which have long been deemed worthless. Negotiations are still pending. We can safely say that rock-ledge from \$50 to \$150 per ton has been discovered.

SAN JOAQUIN.

NEW PLACER DISCOVERIES.—Lodi Review, Dec. 20: A new placer mine has lately been discovered eighteen miles northeast of here, on Goose creek. The discovery was made by Mr. Oscar Barton, who took up 160 acres of Government land for agricultural purposes some time since. There are innumerable small gulches bordering on and along Goose creek, which although dry in the summer, is the bed of mountain streams during the rainy season. Mr. Barton was so favorably impressed with the gold-bearing color of the sand in one of these gulches, that he took an ordinary pan and washed a small portion of gravel, when he found from ten to fifteen "colors." Prospecting tours have revealed samples which, it is estimated, will yield \$10 per day to the man.

SIERRA.

BLOWN UP.—Downville Messenger, Dec. 20: William Toll, while working alone in a tunnel on his mining claim at Monte Cristo, was severely injured, on Tuesday last, by the unlooked-for explosion of a blast which he had put in, and which failing to explode at once, he thought had not ignited. The sequel showed that it had.

TRINITY.

ITEMS.—Trinity Journal, Dec. 20: The weather has been somewhat against the ditch contractors, who are doing well, however, under the circumstances. They have about 140 Chinamen and 25 white men at work on the ditch. Taylor & Superintendent Walker has made a splendid trail to Taylor flat and perfected it by the substantial bridge across French creek. The Don Juan and Dixon Bar companies have water and work has been commenced. Everything looks flattering for a favorable mining season.

TUOLUMNE.

RICH STRIKE.—Tuolumne Independent, Dec. 20: On the Gem mine, west of Columbia, a large boarding-house 50 ft long, for the workmen, has been erected, and a mill building put up, in which will be placed a patent crusher. The incline is down 110 ft on the vein, in good rock. During some necessary changes in the timbering at the top, an astonishing discovery was made. It appears that the timbers were laid upon a vein of exceedingly rich ore, not suspected of being in the vicinity. It is two ft wide, and shows flakes of free gold. Mr. George Morgan is the sole owner. He has contracted with parties below to put in machinery to crush 15 tons of rock in 24 hours.

OSKIN MINE.—The vein has been traced about 1,000 ft, and goes through a hill; the rock something like that of Bodie. The ledge is from 10 to 16 ft wide. There is enough in sight to justify all the expenditures they can apply to develop the mine. They have a shaft 100 ft deep, and are still doing work. The vein is four ft wide.

ITEMS.—Mr. N. Arnold's claim, on Yankee hill, has only been prospected on the top, and \$25,000 has already been taken out. The mining outlook for Columbia and vicinity is improving. The Bodie mine will be started soon, it having been sold to New York parties. Work has already actively commenced on the Continental mine, recently sold to San Francisco parties.

NEVADA.

COMO.—Reno Gazette, Dec. 17: The mills here are running well, and pulp assays high.

OLD MINES REVIVED.—A capitalist from Wisconsin has purchased an interest in the Mountain King mine, McClelland district. Hoisting works have been erected, and they are now down 85 ft on a ledge that can be traced through the mountain. Assays range from \$37 to \$800 per ton.

CLOSED DOWN.—Times-Review, Dec. 20: The stamps of the Grand Prize mill are being hung up, and the work of making the final clean-up of the Belle Isle run commenced. After the clean-up, some repairs will be made upon the mill, which will be in complete running order by the 1st of Jan., when it is reported it will start up again on Argentine.

LENGER DISCOVERED.—Silver State, Dec. 22: The ledge discovered in Winnemucca mountain last week by John Dunn and Judge Ivory, proves to be more valuable than its discoverers anticipated. Samples of the croppings assayed contained \$20.87 in gold and about \$1 in silver to the ton. Mr. Dunn says the ledge is large, and the ore can be easily mined, and he thinks it can be worked profitably.

PURCHASER.—Deeds to nine mining claims, located in the vicinity of the Eagle mine, in Spring valley, purchased by the Van De Water Gold and Silver Mining Co. have been filed for record in the office of the County Recorder this week. These claims are the north and south extensions of the Eagle mine, two locations on the Black Hawk ledge, the Dogus, the Pelican, the Fuzzler, the Troy and the Gladiola.

ARIZONA.

TIPTOP.—Prescott Arizona, Dec. 19: The bottom of the main or working shaft is now 400 feet below the surface and will be driven 100 ft more, as fast as possible; 200 ft of this shaft will pass through new ground. Three winzes, each 10 ft deep, are already sunk. Two more will soon be made at other points on the vein. Fifty men are employed on the various openings. The day is daily abundant, and it will be as soon as the miners get through with the work of tapping the vein at various depths. The Tiptop is a dry mine; hence, the hoisting apparatus has had but little water to draw up.

HASSAYAMPA.—Messrs. Jennings and O'Neal are in from the Hassayampa, where Mr. O'Neal recently struck a large ledge of black sulphurets, which assays \$143 silver and \$7 gold. This find is on the Jennings' lead, and about 800 ft south of the discovery location. Jennings has found some very rich gold float, and is now prospecting for the lead.

CINNABAR.—Mr. Stahl received the other day for assay a piece of cinabar ore from a ledge not far from Prescott which yielded on assay a large amount of quicksilver. The gold in this ore is of a very rich color, and the ledge is large, the quantity of ore probably very abundant, and the percentage of mercury unusually great. This is the first large ledge of the kind, we believe, found in this section, and adds an additional source of wealth to the already vast mineral resources of Yavapai.

VERDE.—John Davis is in town from the Verde. He brought in with him some fine looking specimens of silver ore from a ledge recently discovered by him on the east side of the Verde, which is 50 ft wide on the surface, and

Western Mining Papers.

The influence of the local mining press upon a locality is important, says the *Chicago Mining Review*, perhaps more so than is fully appreciated by such papers themselves. There is now throughout the entire country an active interest in mining, which is growing in breadth and intensity, so that every scrap of reliable news from a mining district is eagerly sought for. It is of the utmost importance, therefore, at this time, that the editors of those journals published in the mining country should most carefully scan every item in regard to mines, strikes, assays, discoveries, etc., that is presented for publication. The people want facts instead of fancy; they demand the actual more than the possible, "the truth, the whole truth, and nothing but the truth."

It may be very pleasant reading for Miner Tom, who has just subscribed for the paper, and wants to purchase a few copies to send East, to read that "Tom's mine is one of the best in this district, and has just struck it rich. Samples assay to the thousands in silver, with a trace of gold. He will probably soon find indications of a true fissure, a mother vein, rapidly widening as he goes down." Such journalism may induce a few other miners to send in subscriptions, in order to read their own names in connection with big strikes, but it at the same time will most effectually turn aside capital that is carefully scanning the field and gathering facts to decide upon a basis of action. Big strikes, large assays and the best mines, have become so common that their announcement has no effect and excites no attention. We have already called the attention of the local mining papers to the importance of giving the particulars of local developments—real growth of mining, and the character and value of ore, mines, and advantages of their respective localities. A letter from a correspondent that reveals wonderful riches in a certain mine, wide vein, inexhaustible supply, rich ore, etc., etc., and condemns all the other mines in the same district as worthless, is certainly suspicious, to say the least, and has no weight with men who, with money in their pockets, are awaiting for facts.

Writers and newspapers West must more thoroughly understand the growing interest throughout the whole country in mining and all that pertains to it, and how capital, backed up by energy and capacity, and shrewd business sagacity, is waiting to be poured into this industry, as soon as the right location is decided upon. Wild stories, extravagant conjectures, flights of fancy as to the possible, pictures of mines yielding double-eagles and diamond rings, have no weight with the men that so many of our mining districts so sadly need at the present time. Such statements and such methods will never attract the class of men to make improvements and confer lasting benefit. There are hundreds of valuable districts as yet untouched, and thousands of as good mines as the best yet opened, all waiting for development. The fate, for years, of many of these localities will be decided by the influence of the Western newspapers. If they grasp the importance and magnitude of the interest they represent, and with liberal spirit devote their energies to the advancement of mining, allowing no selfish or trifling interest to turn them aside from the duty that is due to the cause they have been called to champion, years may be added to the improvements and advantages of the mining country.

The mining interest is so great that it demands a press that shall, in some measure at least, be worthy of its greatness and truly represent it, looking beyond the narrow walls of local or personal interests of the present into the grandeur of its imposing future.

Amalgamated Plates for Placer Miners.

The Butte (Montana) *Miner* says: Operations on Snake river, Idaho, during the past summer have demonstrated to a tolerable certainty that the flour gold abounding in that section of country can be saved by the employment of the silver-plated amalgamating plates. A number of companies have been organized in Salt Lake and elsewhere to work the extensive bars which form the banks of the Snake, and though no extraordinary results have been attained, this availability of a vast area of country for mining purposes has been proven beyond dispute.

The main difficulty has been in getting a sufficient water supply, as a heavy head is required to handle the large amount of gravel necessary to be washed. This trouble overcome, however, it is not uncommon for the operators to clean up from \$10 to \$25 per day to the man. The conspicuous success which has rewarded those who have invested in this proper machinery to work the low-grade deposits of the Snake, naturally leads to the conclusion that an immense scope of country in this Territory which heretofore has been regarded as worthless, can be rendered valuable for mining purposes by the use of the amalgamating plates.

It is generally supposed in Montana that gold diggings are worked out when a man can no longer earn good wages by the rocker or eluice and other old processes of separation. There is a vast amount of surface in this Territory where numerous "colores" can be found, but where the gravel is not sufficiently impregnated with the precious metal to pay by the old methods. The improved plate, lately patented, as manufactured by a California company, have never been

experimented with here, as far as we are advised, and there is little doubt that if the almost barren bars of the Snake can be made to pay handsome profits to those who have taken advantage of the modern invention, the vast extent of auriferous gravel in Montana, wherein gold is found in much greater profusion, will yield returns proportionately larger. It is, perhaps, too late in the year to begin the experiment at the present time, but if the owners of "played-out" placers will invest in the amalgamating plates, it is not impossible that their claims would be in a sense rejuvenated, and that the gold product of this favored Territory would grow to enormous proportions.

Red Mountain Mines.

A gentleman who has just returned from the Red Mountain mines, furnishes the *Virginia Enterprise* with the following account of them:

The Red Canyon mine is situated on the summit of a high mountain in the eastern portion of Douglas county, 21 miles east of Genoa, and by the traveled route 44 miles south of Virginia City. A compass set on one of the highest peaks of the mountain showed the district to lie in a direct line between Virginia City and Bodie, both the Bodie mountains and Virginia City being plainly visible on a clear day.

The only accessible route to the mine for loaded teams at present is from the westward by way of Carson valley, or the Mountain House on the Bodie stage road.

The best route to reach the mines from Virginia City is to go by way of Empire City to Callaghan's bridge, on the Carson river, a distance of 17 miles, thence eight miles by the Bodie stage road to one mile beyond the Valley View, or as some call it, the Twelve-miles House; thence 14 miles to Holbrook's ranch, which is the last stopping place where feed for animals or accommodations for travelers can be obtained. From Holbrook's to the mines is six miles, two and a half miles of which is new road, and has a moderately steep grade, so that but light loads can be hauled over it.

On the eastern slope of the range the mouth of Red canyon lies four miles south of Hine's Hot Spring station. The course of the canyon is nearly east and west, and the mountains on either side are very precipitous and rough. From the mouth of the canyon to the mines at its head is nine miles. There is no wagon road, only a foot trail up the canyon, and in some portions that is almost impassable for anything but the surest-footed animals. Near the head of the canyon the mountains rise very abrupt, the ascent in many places averaging three feet to every yard of advancement.

The summit of the mountain on which are found the principal mines is a broken plateau or table land, from one to three miles in width and seven or eight miles in length. The surface or cap-rock is a soft syenite often and readily mistaken for gneiss granite. On the surface where it is exposed to the action of the elements it hardens, but when penetrated a few feet below the surface is quite soft and seldom requires blasting. The cleavage of the cap-rock is generally from east to west, except lower down on the mountains and to the northward, where outcroppings of porphyry and diorite are shown.

On the outskirts of the district some very large quartz veins have been found, but so far as known what are believed to be the paying ore veins, are small, ranging from three or four inches to four feet in thickness.

These ore veins, for the most part, have an east and west course, with a slight dip to the south and east. The ore is a lively gold-bearing quartz, sometimes very soft and friable, filled with iron sulphurets, often carrying considerable quantities of galena. Assays of gold running up into the thousands are easily obtained, and in some of the veins free gold is often visible to the naked eye. A ready test of the ore is made by pulverizing and panning or horning out the gold, which is often of a very coarse character.

But little work of any value has been done in the district, the deepest shaft of an ore vein being 45 feet. The Warhorse, one of the oldest locations, owned by Messrs. Gray and Carters, worked \$63 per ton in an arrastra, which was started up just at the setting in of winter, but which is now frozen up.

The Knox and Knight, one of the principal claims in the district, is an east and west vein. The float ore from this ledge was first discovered by Thomas Roberts, an old Virginia miner, but the finding of the ledge was left to C. M. Knox, an old resident of Mason's Valley and an old prospector. This ledge has been traced for a distance of 3,000 feet or more. The four principal locations are the Knox, the Knight, the North Star and the Morrison, all of which show good ore.

There is an abundance of wood and water for milling and other purposes within a range of five or six miles of the mines. All that is needed to assure its permanent prosperity is for the owners to sink on their ledge and prove that they are true and continuous veins, and that the richness of the ore holds out as depth is attained.

There are now only about a dozen prospectors in the district, and but little can be done in the way of work before spring, as at this time the summit of the mountain is covered by a foot or more of snow. There are no accommodations, and as the altitude is great, it would be useless for those thinking of going there to attempt to do so before the opening of spring.

Effects of Heat on Men in Mines.

In an interesting paper at the Pittsburgh meeting of the American Institute of Mining Engineers, Mr. John A. Church reviewed, at considerable length, the accidents in the Comstock mines and their relation to deep mining. In several instances miners have been fatally scalded by falling into the hot mine waters, which exhibit temperatures rising to 158° Fahr. The most remarkable casualties, however, are due to the killing effect of labor in the hot and steaming atmosphere. The proportion of fatal casualties is larger in this class than in any other, being 73%; and from the peculiar mental effects of the heat it is highly probable that it may be the real cause of many mishaps, which, under other circumstances, would be ascribed to culpable blundering.

On the 1900 level of the Gould & Curry mine, a drift was run along and quite near to the black dike, one of the hot spots of the mine. At a spot where the thermometer marked at times 128° Fahr., Thomas Brown fainted while at work. When taken to the surface and revived, he was found to have completely lost his memory. He could not tell his name or where he lived, and had to be dressed and taken home by his friends. The newspaper which recorded the occurrence said that such sudden loss of memory from overheating was quite common in the mines; and suggested that the fact might furnish an explanation of the walking off into fatal winzes and chutes by experienced miners, seemingly with deliberated intention.

A frequent accident in these mines is fainting in the shaft while the cage is rising to the surface. The faintness is always felt immediately upon reaching the cooler air, 100 or 150 feet from the surface, where there is usually a side draft through some adit. This happens so often that a man who has been working in a hot drift is never allowed to go up alone. Long habitude to the heat is no safeguard against this danger, and serious accidents have occurred in this way.

Among minor casualties, Mr. Church mentions one which happened to Mr. Sutro, in the Sutro tunnel, before it made a connection with the Savage mine. After spending some time in an air temperature of 110° Fahr., Mr. Sutro went to the air pipe to cool off. He stayed so long that the miners told him to get away from the pipe and let them have air. He did not move, and when they tried to stir him up with the handles of their shovels they found him unable to move. He had lost all volition, and had to be taken out on a car.

The graver results of overheating include insanity and death. The death of a carman on the 1400 level of the Caledonia mine, Gold Hill, March 11th, 1878, is a case in point. He had been idle for six months, and that morning he was working his first shift. At an early hour he rushed into the station of the 1400 level and reported that the wheels of his car were smashed. The station master returned with him to his car and found it all right. There was evidently something wrong with the man, and he was taken to a cooling place. Here decided mental aberration was discovered, and the man, firmly lashed to the cage, was hoisted to the surface, where he fainted at once and died in a few minutes. In this case the heat was only about 90° Fahr.

In another case a miner died from cramps, attributed to heat, but which may have been due to drinking iced water; and another death is charged to a cold taken while cooling off after being partially overcome with heat.

Though contrary to the rules of outside hygiene, the miners resort to copious drafts of ice water or to exposure to strong cold air currents for recovery from overheating, and usually with impunity. The cold air cooling is considered the safer method, but to gain time Mr. Church commonly chose the ice water, and never felt any ill effects from it. With several thousand cases a day of rapid cooling off by one or the other of these methods it is surprising that fatal consequences have been so infrequent.

The next case illustrates the violent effects which excessive heat may have upon a person not accustomed to it: "On Friday, October 11th, 1878, John McCauley went to work for the first time in the Imperial mine. He was cautioned against overexerting himself in the extreme heat of the lower levels. He replied that he thought he was strong enough to stand anything, and paid no attention to the advice. At half past two in the afternoon he was brought to this surface in an unconscious state, and died the next morning at half past ten o'clock." Two other cases very similar to this have occurred in the Imperial within a few years. This mine is excavated in one of the hot spots of the Comstock.

The hot drift on the 1900 level of the Gould & Curry is the scene of the most serious of these casualties due to heat. Five men were sent there in June, 1878, to load a donkey pump on a car. The work was so exhausting that when the pump caught on a plank they were not able to move it. They seemed to have been in a state of mental confusion, but felt that they could not remain longer. Starting up a winze which connects with the 1700 level, one man fell on the way, and the others were afraid to stop to help him, but pressed on, reaching the 1700 level in half an hour from the time they left it. They were very confused and nearly speechless, and hardly realized what had occurred. Three men went down to the rescue and found the fallen man still alive. Clearing

the pump they got into the car and signaled to hoist, but on the way up the man they had gone to rescue reeled and fell off. The car was stopped at once, but he was jammed between it and the brattice so fast that the others left him and went for help. They all gave out, two half way up, and the other just as he reached the 1700 level, where a friendly hand pulled him up. A new rescue party went down and found two men dead, and the third died soon after. The shift boss reports that "the accident was due solely to the heat, as the air is good enough and pure enough, barring this heat." The winze was not an abandoned one, but in daily use. A heavy volume of steam is reported to rise through it from the 1900 level, the temperature of which at the time of this accident, is given at 128° Fahr. Mr. Church gathers from the detailed account that the death of the men is possibly attributable to the fact that when the miner fell off the car the latter was stopped in a place that was hotter than the rest of the winzes. It is to be regretted that no adequate studies have been made upon the precise physiological phenomena presented by death under these circumstances. The legal requirements are satisfied when it is proved that the casualties are due to heat.

PLACER COUNTY MINES.—The *Placer Herald* says: We have received from Frank X. Lavallo, Superintendent of Pugh's quartz mill, Ophir, a statement that speaks more for the quartz lodes of Auburn and Ophir districts than any amount of praise in general terms could do. Fulsome praise and prompted puffs are good as far as they go, but facts and figures, after all, are what afford consolation to the inquiring mind, and here we have them: This mill runs almost entirely on custom ore, and hence its crushings include rock from nearly every ledge in this and Ophir districts. For the year from Dec. 1, 1878, to Dec. 1, 1879, the amount of rock crushed was 1,120 tons. From this rock there were obtained 1,397 ounces of retorted gold, or about one and one-fourth ounces to the ton, an average that we don't believe the quartz ledges, taken indiscriminately as this showing takes them, of any part of the State will equal. Allowing the low estimate of \$14 per ounce, this would give a yield of \$17.50 per ton, on an average, for all the rock taken out by the prospectors during the year, assuming that the rock crushed at the other mills will compare with the rock crushed at this, and there is no reason for believing it is any different. We often think, and this showing goes to strengthen the idea, that if the quartz veins that rich this country from Penryn to Clipper Gap or Colfax, were known to exist in some far off country, remote from civilization and difficult of access, the whole civilized world would become excited over them, thousands of men would risk their accumulations, and even their lives to reach them, and capital by the millions would pour in from all parts of Christendom to work out their development. It must be admitted, after all, that there is with men, as with women, a peculiar charm about that which is most difficult to reach and hardest to obtain.

BODIE MINES.—The *News* says: Every day the work of opening up and developing our mine is continued with the most encouraging results. Of course it must not be expected that every shaft will prove a mine, yet there can be but little question that those lying on the great mineral belt will prove valuable properties. Were the Noonday, Booker, Queen Bee, University, Addenda, Red Cloud, Maybell, Dudley, and many other mines directly on the lead and showing fine bodies of ore, located in Virginia City, their stock would be selling at quadruple what they are doing on the boards to-day. There is no mine in Virginia City that shows this large body of paying ore uncovered in the Noonday; there is none that shows the quantity of high-grade ore in the Addenda with as good a prospect of its opening out into a rich bonanza. None can tell what may yet be uncovered, but from the strong formation and the solidity of the ore body it is reasonable to infer, being 26 feet wide, that it must continue as the Standard rich ore, having but slight changes in quality. On Bodie Bluff the outlook is equally cheering. That the Tioga will open up a mine when a proper depth has been attained all indications go to prove. The Bechtel is now in a fine body of ore, whilst the prospects of the Jupiter are in the highest degree encouraging. The McClinton, Con. Pacific and Mono have the most favorable prospects, whilst the Blackhawk, with a fine vein of bright, lively ore, and in a good, strong formation, gives evidence that depth must be attained before they can uncover a mine.

IN RUSSIA, at the present time, there are 205 distinct establishments engaged in the manufacture of agricultural machinery. Eighty are driven by steam power, seven by water power, ninety by horse power, and the remainder by hand power. From the description of the power employed, it is reasonable to suppose that most of these establishments are on a small scale.

BLAST FURNACES IN GREAT BRITAIN.—The *Iron Trade Circular* of recent date publishes a detailed list of the blast furnaces in and out of blast in Great Britain. The list is arranged by counties, and foots up—456 in blast, 493 out of blast, or a total of 949.

Detestable Frauds.

The innumerable swindlers who operate through the mails are being made known through the Postoffice authorities. The *Western Rural* prints an alphabetical list of names which represent people whose letters the Postoffice officials have ordered retained in the hands of the Postmasters of the several towns because the parties are doing a fraudulent business through the mails. It would be well for our readers to preserve this list for reference, and whenever they see an advertisement of questionable character, to examine the list and ascertain if it contains the name or names of the advertiser or advertisers. The list is as follows:

Allen, H. D. P., alias W. T. McCall, National Banking Co., New York city.
American Coral Co., Pittsburg, Pa.
Arizona Lottery, Prescott, Arizona.
Bartlett & Co., B. C., Gloucester, N. J.
Bennington & Co., A. B., alias Jace Marks, Lansing, Iowa.

Benton, D. V., Laramie City, Wyo.
Bishop, L. D. S., Cincinnati, Ohio.
Brain, John C., alias Excelsior Mfg. Co., Sheffield Fire Arms Agency, New York city and Chicago.
Bristol Piano Co., New Bedford, Mass.
Burrow, John, Bristol, Tenn.

Burnett, H. A., New York city.
Coldwater, Michael, Prescott, Arizona.
Clark & Co., alias Silver Mining Co., New York city.
Cosmopolitan Stamp Co., alias Philadelphia Stamp Co., Giovanni Patroni, Philadelphia, Pa., and Camden, N. J.
Crest, John, alias W. J. Hill, C. H. Walker, C. Wade, Elkhart, Ind.; Augusta, Mich.; Battle Creek, Mich.

Eastern Manufacturing Co., Boston, Mass.; Rockland, Me.; Chicago, Ill.
Egerton & Co., Camden, N. J.
Edmunds & Co., J. E. Webster, Mass.

Eggleston, Edward A., Rosita, Cal.
Ellis, Ella H., alias Russell & Co., New York city.
Florence Jewelry Co., Pittsburg, Pa.
Franklin, George W., Louisville, Ky., and Glasgow, Ky.
Freshman & Co., Pittsburg, Pa.

George & Co., Jax W., New York city.
Gustavus & Co., E., alias F. E. G. Lindsay, Holston, W. Va.
Hall & Co., H. J., Baltimore, Md.

Hall & Co., J. H., New York city.
Hamilton & Co., J. E., New York city.
Heister, Charles E., alias U. S. Syndicate, New York city.

Henry & Co., J. C., alias Clarence W. Miller, Glen Falls, N. Y., and Chester, Pa.
Hill, W. J., alias C. W. Whitney & Co., Elkhart, Ind.

Augusta, Mich., and Battle Creek, Mich.
Hurlburt, William H., alias Western Gun Co., Chicago, Ill.
Jones & Son, A., Hopkinton, Mass.

Jones, Edgar W., alias Harry J. Littleton & Co., Union Purchasing Agency, Union Publishing Co., Magnetic Watch Co., Ashland, Mass., and South Framingham, Mass.

Kentucky Land Co., Louisville, Ky.
Leavitt & Co., alias Russell & Co., Sunbeam Publishing Co., New Bedford, Mass.

Lindsey, F. E. G., Holston, W. Va., and Abingdon, Va.
Littleton & Co., Harry J., Ashland, Mass., and South Framingham, Mass.

McCall, W. T., New York city.
Mages, John W., Laramie City, Wyo.
Magnetic Watch Co., Ashland, Mass., and South Framingham, Mass.

Marks, Jace, La Crosse, Wis.
Miller, Clarence W., Chester, Pa.
National Art Co., Cincinnati, Ohio.

National Banking Co., New York city.
Paris Novelty Co., Boston, Mass.; Rockland, Mass.; Chicago, Ill., and Camden, N. J.

Pattee, J. M., Manager, Cheyenne, Wyo., and Topeka, Kan.
Premium Art Co., Pittsburg, Pa.

Reade & Co., New Haven, Conn.
Royce, J. M., Grafton, W. Va.
Russell & Co., New York city.

Russell & Co., New Bedford, Mass.
Russell, Hopping & Co., Riverside, N. J.
Silver Mining Co., New York city.

Sine, L. D., alias L. D. S. Bishop, Cincinnati, Ohio.
Sineburn, E. Ellsworth, alias Paris Novelty Co., Eastern Manufacturing Co., Boston, Mass.; Rockland, Mass.; Chicago, Ill.

Stewart, Frank, Philadelphia, New York.
Sunbeam Publishing Co., New Bedford, Mass.
Texas Gift Concert Association, Dennison, Texas.

Tomlinson, James A., New York city.
Tyner & Co., J. C., alias American Coral Co., Florence Jewelry Co., Freshman & Co., Premium Art Co., Pittsburg, Pa.

United States Syndicate, New York city.
Union Publishing Co., Union Purchasing Agency, Ashland, Mass.; South Framingham, Mass.

Union Silver Plating Co., Cincinnati, Ohio.
Wade, C., alias C. H. Walker, Elkhart, Ind.; Augusta, Mich.; Battle Creek, Mich.

Webber & Co., alias National Art Co., Union Silver Plating Co., Cincinnati, Ohio.

Western Gun Co., Chicago, Ill.
Whitney & Co., C. W., Glen Falls, New York, Chester, Pa.

Wilcox & Co., Windsor, Pa.

THE OIL RESERVOIR IN MOODY'S GULCH.—The location of this newly-developed "mine of wealth" is in the township of Lexington, about one and a half miles southeast of Alma station, on the Narrow-Gauge railroad, Santa Clara county. The success of this enterprise is due to the unbounded perseverance of Mr. McPherson, the President of the company lately organized for the purpose of prospecting. Mr. McPherson came to California about four years ago, as agent for Farrar & Co., of Buffalo, N. Y., manufacturers of engines and boring apparatus, for the celebrated oil district of Pennsylvania. He turned his attention first to the Los Angeles district, where he spent his efforts and money without success. That he is now about to reap the reward of the patient application of years is a matter of congratulation to his many friends. Soon after reaching a depth of 780 feet, which required five or six months' hard labor, the out-pouring stream of petroleum ascended to a height of 100 feet above the surface of the ground, pouring out a waste of 100 barrels before it could be stopped. Oil is now being pumped at the rate of a barrel an hour. If this discovery reaches the proportions that it is confidently believed it will, the Narrow-Gauge Railroad Company will, not unlikely, build a branch road to the well or wells, from Alma station. Preparations are already completed to commence the second well.

USEFUL INFORMATION.

OXIDATION OF IRON AND STEEL WHEN IN JUNCTAPOSITION.—In a paper read before the Iron and Steel Institute, at its recent Liverpool meeting, Mr. G. Radcliffe incidentally mentioned a case in which steel boiler plates had, when exposed to the same circumstances as adjoining iron plates, distinguished themselves by pitting more than the latter, the steel plate next to the iron being oxidized considerably more than any other. The following analysis by Mr. Edward Riley gives the chemical composition of the steel:

Carbon	0.330
Silicon	0.102
Sulphur	0.005
Phosphorus	0.005
Manganese	0.515
Copper	0.053
Iron	99.920

Mr. Radcliffe's conclusion, although he does not distinctly state it, is that it will not do to place iron and steel side by side.

SEAO BOILER COVERING. Mr. Franz Buttgenbach, the well-known metallurgist, gives the following method for the nitilization of blast furnace cinder as an insulator for steam pipes, etc.: Mix 150 parts of cinder dust, 35 parts by weight of fine coal dust, 250 parts of fire clay, and 300 parts of fine dust, with 10 parts of cow's hair, add 600 parts of water into which 10 to 15 parts of raw sulphuric acid has been poured, and make a stiff dough of the whole. This is thrown in small amounts upon the warmed pipe, hardening rapidly. Upon this rough coat, a second, third, etc., is laid according to the thickness which is to be used. By the action of sulphuric acid gypsum is formed, and the silices, rendered free, hardens. The mass becomes as hard as porcelain, and is still porous. It adheres firmly, and never cracks. Mr. Buttgenbach states that he has tested its merits by ten years' use, and has found it to meet all requirements.

SILVERING MIRRORS.—Some time since the Academie des Sciences offered a prize of 2,500 francs for a method of satisfactorily and permanently silvering mirrors, and which should save the workmen the danger of exposure to the effect of mercurial vapors. The prize has been awarded to M. Lenoir, whose process is substantially as follows: The glass is first silvered by means of tartaric acid and ammoniacal nitrate of silver, and then exposed to the action of a weak solution of double cyanide of mercury and potassium. When the mercurial solution has spread uniformly over the surface, fine zinc dust is powdered over it, which promptly reduces the quicksilver and permits it to form a white and brilliant silver amalgam, adhering strongly to the glass, and which is affirmed to be free from the yellowish tint of ordinary silvered glass, and not easily affected by sulphurous emanations.

DESTRUCTION OF CAST-IRON GAS MAINS.—A curious case of deterioration of cast-iron gas pipes has recently been observed at Saarbrücken. The pipes in question had been laid for 10 years, and when removed were found converted into a soft substance which could be cut with a knife, and, on analysis, was found to contain only 52% of metallic iron. The pipes were laid in channels cut in soft sandstone, filled in with ashes from locomotives. The coal which produced these ashes was from the Saarbrücken basin, and was relatively rich in sulphur. The destruction of the pipes was most probably due to the action of the sulphur contained in the ashes, combined with the oxygen of the atmosphere. This view is supported by the fact that the substance into which the pipes had been changed contained 14% of sulphuric acid. A large number of pipes were completely destroyed and had to be renewed.

PHOTO DECORATION OF METALS.—Herr Falk's photographic method consists in coating the metallic surface with a photographic film, which is then exposed under a transparent positive; by this arrangement the parts lying beneath the dark places of the positive are not affected by the light, and are consequently capable of being etched. With curved surfaces a print taken in fatty ink on paper by a photographic method is transferred to the metal, and all the parts covered with the ink are by this means protected from the etching. It is a peculiarity of this process that the etching fluid colors all the etched places black, and this adds considerably to the effect of the whole.

A BRILLIANT PURPLE FOR SHOW BOTTLES.—Sulphate of copper, two drachms; water, two ounces; French gelatine, one drachm; boiling water, two ounces; solution of potassa, two pints. Dissolve the copper salt in the water, and the gelatine in the boiling water. Mix the two solutions and add the liquor of potassa. Shake the mixture a few times during ten hours, after which decant and dilute with water.

THE DEEPEST DIVING.—The deepest depth to which the diver has descended in pursuing his dangerous occupation, was that reached in removing the cargo of the ship *Cape Horn*, wrecked off the coast of South America, when a diver by the name of Hopper made seven descents to a depth of 201 feet, and at one time remained down 42 minutes.

ACTION OF SEWER GAS ON LEAD, ETC.—The sanitary inspector of Dundee, Mr. T. Kinnear, has watched the effect of the gas on portions of the zinc eaves of buildings where it was striking on the under part, and found, in the course of a couple of years or so, pretty large holes eaten completely through, showing that material could not long withstand the effect of the gas. Lead is, of course, more durable than zinc, but the difference is only a question of degree, as shown by the fact, in not a few of the waterclosets repaired by the officers of the department during the year, small apertures were found in the main vertical lead pipe, and in the cross or horizontal one leading from it to the trap of the closet various perforations were found on the top, indicating clearly the operation of foul air from the drain. Lead traps and soil pipes from waterclosets, baths and fixed basins are all subject to wear and tear; but the traps, being burdened with the additional strain of barring the passage of sewer gas, do their work less efficiently, and for a much shorter period than they are generally credited with, hence the necessity for proper ventilation and occasional inspection.

TREATMENT OF GOLD-FISH.—Seth Green says this as to the proper care and treatment of gold-fish: "Never take the fish in your hand. If the aquarium needs cleaning, make a net of mosquito-netting and take the fish out in it. There are many gold-fish killed by handling. Keep your aquarium clean, so that the water looks as clear as crystal. Watch the fish a little, and you will find out when they are all right. Feed them all they will eat and anything they will eat—worms, meat, fish-wafer or fish-spawn. Take great care that you take all that they do not eat out of the aquarium; any decayed meat or vegetable in water has the same smell to fish that it has to you in air. If your gold-fish die, it is attributable, as a rule, to one of three causes—handling, starvation or bad water."

A USEFUL COPPER ALLOY.—A very useful copper alloy, which will attach itself to glass, metal or porcelain, may be made as follows:—From 20 to 30 parts finely blended copper (made by reduction of oxide of copper with hydrogen or precipitation from solution of its sulphate with zinc) are made into a paste with oil of vitriol. To this add 70 parts of mercury and triturate well, then wash out the acid with boiling water and allow the compound to cool. In ten or twelve hours it becomes sufficiently hard to receive a brilliant polish and scratch the surface of tin or gold. When heated it becomes plastic, but does not contract on cooling.

GOOD HEALTH.

Brain Growth.

The question is often asked: "How long does the brain of an individual continue to grow?" Some have an idea that it attains its full growth at the age of 20 years; and we have seen assertions, professing to be from medical authority, that the brain attains its growth at about 14 years; but no close observer, no phrenologist who has had opportunity to measure thousands of heads, and to measure not a few of them, say once in five years for twenty-five years, will believe a word of it.

In many cases the brain will increase in size till a man is 60 years of age, provided he have a healthy, vigorous body, and live correctly, so far as diet and labor are concerned, and the mind be kept in an active, but not over-excited state.

Any sharp observer may enter 50 churches in succession, when the congregations are full, and he will readily see that the gray-headed father, sitting at the head of his family with his son 25 years of age by his side, will have a considerably larger head than his son. In numerous cases this can be remarked in looking up and down the aisles. The old gentlemen's heads are the largest. If we revisit the same church 30 years afterward, we will find the energetic son with gray hair sitting at the top of the pew, and his son at his side; and the older man will have a head larger than the hopeful son—showing that it had been growing up to 50 years of age or beyond. We have just received a letter from Mr. L. N. Fowler, of London, which contains one remarkable passage. Mr. Fowler says: "I shall send you soon the phrenological character of Sir Josiah Mason, of Birmingham, England. In 1864 I measured his head, which was 23½ inches; in 1869 it measured 24 inches; and now, in 1879, it measures 24½ inches, plump; and he is now in his 85th year."

The law of growth, in respect to the brain, is the same as that relating to growth of body. If a muscle, or set of muscles, be called into frequent and efficient exercise, they become thereby hungry for nutrition; and when the blood is passing those parts, the nutriment carried in the blood is absorbed by the parts needing it, and they become enlarged. A broken bone needs at the point of fracture bone-making material, and the blood which carries nutrition for every part, as it passes the region of the fracture, loses by affinity the material which the bone wants to repair the fracture. As the blood passes a flesh-wound, that part of the blood adapted to heal the wound is taken up and used where it is required. Let a person exercise the brain in the intellectual or thinking region and the forehead will grow, while other parts remain stationary. Persons engaged in rough, laborious business need the exercise of the base of the

brain, and that part of the head will grow; but if the labor require also the active exercise of the intellectual organs, the two regions will become enlarged accordingly. Those who devote themselves mainly to moral and esthetical subjects will be found with a larger top-head; and those who have body enough to give adequate support to the whole system, including the brain, will be able to increase the size of the brain year by year by the general exercise of all the faculties until old age. The body increases in size in old age, why not the brain? Generally there is not vigor enough in the vital system to sustain the body and push the development of brain beyond the age of 50; but there are cases which we happen to know, proving brain growth until after 60 years of age.

Some persons think it impossible for the brain to increase in size after the bones of the skull have become hard and strong. When the brain requires more room in any part, the bone material of the skull is gradually absorbed or dissolved, and, like lime-water, is taken up by the circulation to be reorganized into new adjustments of the skull, large enough for the brain. The clam shell is as thick as a human skull and much harder, yet a clam will double his size in two or three years, during which time the entire shell will have been reconstructed on a larger pattern in every direction. The clam is never imprisoned or cramped by his shell; he is, like the brain, simply protected and shielded as by a friend. The shell is alive, and so is the human skull, like the finger nails, or the hoofs of animals, and capable of rapid growth, though the process be to us imperceptible.—*Phrenological Journal*.

Appearances of the Tongue in Gastric Disorders.

Dr. Wilson Fox gives, as valuable aids in the diagnosis of gastric disorders, the following conditions of the tongue:

1st. Dyspepsia, with distinct atony of the stomach. The tongue broad, pale and flabby, the papillae generally enlarged, more especially at the tip and edges.

2d. Dyspepsia from irritative causes. The tongue is redder than usual; often of a bright florid color, or even raw looking. It is often pointed at the tip, which, together with the sides, presents an extreme degree of injection, the papillae standing out as vivid red points. This form is often associated with aphthae, and is most common in scrofulous children and phthisical adults.

3d. Dyspepsia from excessive or hurried eating is apt to present a tongue uniformly covered through the greater part of its surface with a thick fir, whitish or brownish, with some degree of enlargement and redness of the papillae at the tip and edges.

4th. Neuroses of the stomach display a tongue which, as a rule, is clean, though often pale, broad and flabby.—*Lancet*.

SETTING THE MAD TO CURE THE MAD.—Atan asylum in Vienna (says the *Union Medicale*, quoting from the *Danube*) a novel method of treatment has been adopted. The director has established a lithographed journal for circulation in the asylum, and he induces the patients to contribute to it. Especially he encourages them to refute the manias of their comrades. The man who believes his nose to be made of sugar candy and liable to dissolve, he says, can argue with excellent logic against the folly of his friend's theory that his beard is a tender plant and needs frequent watering. As a rule, they are able to discuss with good sense all subjects except those which concern their peculiar delusion.

A NEW THERAPEUTIC AGENT.—A new method of treating cancerous growths, tumors, etc., consists in subjecting the parts to a stream of hot, dry air. This is proposed and has been successfully applied by Dr. G. A. Keyworth, of England. By means of a foot bellows he caused air to pass through a glass vessel containing calcic chloride, then through a heated iron tube, and thence directed the hot, dry air against the surface of a cancerous sore. The treatment was continued for an hour, the effect being to relieve the pain and cause the parts heated to shrink and dry up very considerably. It is believed that this new method will prove valuable when proper appliances are employed to maintain and direct the supply of the air.

CONGESTIVE HEADACHE.—The use of the old domestic remedy, a tight bandage, during the attack is useful. I make use of a rubber bandage, applied thoroughly from the eyes up, with a thin pad over each temporal artery, if the temporal ridge be sharp enough to keep the bandage from compressing the arteries. Instead of rubber, a well applied muslin bandage may be put on and then wetted, using compresses over the temporal arteries. The comfort thus given is sometimes surprising.—*Sanitarian*.

A NEW DANGER FROM RABBITS.—Referring to a recent death at Kerang from hydatids of the liver, a correspondent of the *Bendigo Advertiser* states that the rabbit nuisance is likely to soon come to the front in another form, it being an expressed medical opinion that this disease, which is another name for fluke, is spread by the use of rabbit's flesh for human food.

TO NEUTRALIZE THE sting of a gnat or mosquito, French sportsmen rub the part affected with a little cerumen, that is, the wax of the ear, extracted by the little finger.

The Week.

The topic of conversation just at present is the unusually cold spell which has come upon us, and which seems to have extended over the whole coast. The Oregon rivers are frozen over, and Washington Territory and British Columbia are ice-bound. Thermometer 32 degrees below zero in Washoo, and ice all over the country. Wednesday was the coldest day in San Francisco since the establishment of the Signal Service station here in 1870. At 5 A. M. the thermometer was 34 degrees, and the highest point during the day was 44 degrees. The mean temperature was 39. In some instances the water pipes were found frozen, a most unusual circumstance among us.

There has been a sort of lull in general business, which is usually attendant on Christmas week. The people have donned holiday attire and thronged the streets intent on Christmas purchases, and it is not likely they will settle down into the humdrum of every-day work till after New Year's.

The mining news of the week is barren of much interest. The Comstock is depressed, and stocks are down. The California miners will rejoice at the cold weather, which will lock up a store of water for the spring washing and make flush times with them. The mining "boom" in the East still continues, but more attention is being paid by Eastern investors to the Black Hills, Colorado and Arizona than to California or Nevada, so it has been of very little value to us as yet.

PROTECTION OF MINERAL LANDS.—The Secretary of the Interior has rendered a decision that whenever, prior to patenting, it is discovered that land previously offered and entered as agricultural is really mineral in its character, the entry must be cancelled and the land reserved for entry under the laws especially applicable to mining lands. The issue was presented by the case of Smith Scoggin vs. Culver et al., involving a tract of 2,000 acres of land in Camden (Arkansas) district, which was purchased from the Government on private entry in April, 1878, but was subsequently found to contain argentiferous lead ores.

Close of the Volume.

With this number the MINING AND SCIENTIFIC PRESS closes its thirty-ninth volume. It has been so many years an exponent of this mining industry of this coast, that its position has long been recognized as one of the factors in mining and metallurgical progress. In both dull and prosperous times, during excitements and lulls, we have striven to uphold the interests of legitimate mining and disseminated such information as would be of value to our readers.

The copious index, which fills the last page of this paper, is a sufficient indication of the scope and variety of the subjects treated during the past six months, to convince any one of the trouble we have taken to collate miscellaneous technical information of every kind.

As far as mining matters are concerned we have kept track of developments in the mines, both great and small, of all districts on the coast, giving a page and a half of condensed news each week from the various districts. We have also kept close watch of all improvements in either mining or metallurgy; both at home and abroad, so that all our readers will know what others are doing in their own line. The mechanical industries of the coast have also received close attention and we have described all the mechanical improvements of note emanating from our shops and all the large machines made by them.

This journal is certainly worthy of the continued support of the progressive, industrial classes of this coast. It has long been with them and for them. The miners particularly ought to second our endeavors with subscriptions and correspondence. An improvement or benefit to one is an improvement and benefit to all, and we can tell all what one is doing.

The PRESS enters on its twentieth year with renewed vigor and strength. The long experience of its proprietors and editors in editing and publishing a technical journal must result in benefits to the readers, and all of our energy will be concentrated in making the PRESS a welcome weekly visitor to the mine and the shop. All that we ask is the co-operation and assistance of those to whose interests we are devoted, and we feel that both will be extended to us in the future as in the past.

California and the Comstock.

Because the quotations of stock of the Comstock mines come from San Francisco, and so many of the owners of the principal mines of that lode reside here, a great many people in the East have an idea that the "Comstock" is a sort of group of mines somewhere within the boundaries of California. It was only last week that a weekly paper, published in this city, in complaining of the use of the diamond drill on the Comstock lode, called on the Legislature of California to remedy the evil and make the Comstock miners, in Nevada, stop using it. In fact so intimate is the connection between the Comstock and San Francisco, that those who do not stop to think suppose it is a California institution.

In the East, with this impression, the present "deadness" of the Comstock is doing great injury to California. A good many think because the Comstock is nowhere in bonanza just now, that the whole bottom of California mining has dropped out, and they, therefore, turn their attention to Dakota, Colorado and Arizona to the neglect of California mines.

The evils of stock gambling are also cited against us, and eight out of ten Eastern people think our Stock Boards work principally on California mines, and that such mines are mostly stock-johning enterprises, with more paper than ore. They do not, in buying or investing, care to interfere with such properties.

The facts of the case are that very few California mines, indeed, are listed on the Stock Board, and those few mainly belong to Bodie, out of which district the brokers hope to see a second Comstock. The bulk of the mines in this State are worked by individuals or private companies, and for what they are worth, rather than for any fictitious value placed upon them in open market by brokers.

"The hills look green afar off," and people will always run after things at a distance in preference to better ones near at home. At the same time there is a certain set of people here who know good things when they see them, and these keep on the lookout for exceptionally rich mines within our own borders. That the California mining industry should bear the stigma of being a sort of grand stock jobbing enterprise is very unjust, since only a very small number of California mines are "dealt in" in our stock market.

BUTTE HYDRAULIC MINING CO.—Zotique Gervais has commenced suit in the Twelfth District Court to prevent the Directors of the Butte Hydraulic mining company from collecting an assessment of \$10 per share on the capital stock, and also to compel them to render an account of their actions in the purchase of a dredging machine from the American Dredging company for \$20,000, which machine is alleged to be utterly worthless. Gervais charges that the Directors of the Butte company were personally interested in the contract for the dredger, and in the purchase of it have defrauded the company.

Copper Rolling Mills Needed on this Coast.

There has never been a period during the existence of this mining industry of this Pacific slope in which a more propitious time could be found than the present for the establishment of rolling mills for the production of the various marketable forms of copper. The workings of the copper mines of the world have heretofore produced so large a supply as to greatly exceed the demand, and the result was seen in the reduction of the price, which placed a check upon them. But the demand has so greatly increased, owing to the enlarged requirement for articles of copper both in the arts and in domestic uses, that the price has already advanced over 40% for ingot copper, that being the form in which the metal is put upon the market, and from which all subsequent forms are produced; and the recent sales which have transpired in the Eastern markets, of copper to arrive in February, have been made at still further advance.

The copper mines of this coast, as has been shown in recent numbers of the PRESS, are now being brought into activity, and those now worked are producing an ample supply for extensive rolling works. On this score there need be no apprehensions of an insufficient yield to keep more than one large establishment fully employed. Prominent among the copper mines of this coast are the San Francisco Copper Co.'s mine; the Battle Mountain mine; the Newton copper mine; the Eagle copper mine, and several others. The San Francisco can produce about 60 tons per month of precipitated copper; the others could probably be wrought up to a similar quantity, if not to a greater amount. Besides those named there are many mines that would be worked to advantage if there was a home market for the copper or for the ore. The expense of sending the ore abroad to be reduced to metal has been, and still is, so great as to amount to a prohibition of shipping it, except in choice lots of exceptionally rich ore. Low grade ores would entail a loss to the shipper who should send them abroad; while if reduction and rolling works were established at some central point, even the moderate profits which accrue to the miners from their sale, would be a sufficient inducement for the continued development of the mines, more especially when the hope of obtaining a higher grade of ore was at all reasonable. The better price which they would obtain by the sale of the mats, or of the precipitates, at the reduction works, combined with the more speedy and economical character of the transit to them, would also conduce to a still greater activity in the mining department.

No one rolling mill would be able to work up all the metal that would be produced; this industry once inaugurated other mills would be called into existence to work up the accumulating copper. Nor would this be detrimental to the first in the field. The copper consumed on this coast would demand the full working capacity of several mills to supply the needed quantity. Even if an excess over the home demand should be produced, the inter-continental markets would be open to the producers, and they could be supplied at lower rates from this section than from elsewhere, on account of the facilities of production and the difference in freight charges.

Sheathing metal could be sold here at a much less price than now rules, and afford a fair business profit to the manufacturer; a reduction in its price would lead to an enlarged consumption; the same might be said with truth in regard to bolts, rivets and nails. Our factories and mines consume a large amount of rivets for their belting, and their sale alone would be a leading feature in the trade.

The field is a wide one, and as our industries thrive and our population increases, there must be a corresponding increase in the demand of manufactured copper. This branch of industry presents unusual attraction for the investment of capital, not only from the certainty of sale of its manufactures, with an increasing market, but also from the fact that the intrinsic value of the material used cannot deteriorate while the goods are on hand.

Arrangements are being made by which full details of the cost of constructing the furnaces and rolling mill, and the attendant expenses of running them, will be set forth in the columns of the PRESS, when those interested in the matter can see what the cost and profit both will be, and it is to be hoped that the enterprise will be regarded with favor by some of our energetic capitalists. If the work is conducted with proficient knowledge and rigid economy it cannot fail of being a success.

EDISON'S ELECTRIC LIGHT.—Edison gave a private exhibition of his newly invented electric light on Christmas eve. A Chicago Journal dispatch says: The workings of the light and lamp in the residence of Mr. Edison were completely successful, and people will be both astonished and gratified at the result of the public exhibition soon to be given. The successful operation of the light at Edison's residence makes it appear that matches will be things of the past in cities where the light becomes fairly established, while those who are manufacturing piping, chandeliers and globes, now necessary in the use of gas, must find other industries.

Working Auriferous Silver Ores.

[From Kustel's "Roasting of Silver Ores, Etc.," Second Edition.]

Ottokar Hofmann's Patent Process.

If rich auriferous silver ores, in which the percentage of gold is high, almost equal to that of silver, should be subjected to a chloridizing roasting, then impregnated with chlorine gas, leached with water, for the purpose of extracting the gold, and finally leached with hyposulphite of lime for the silver, it would in this case, although a high percentage of silver might be extracted, result in a yield of gold that would hardly amount to much more than about 50% more or less. The reason is not easily explained, the gold may be influenced somehow by the base metal chlorides during the roasting which prevent the gold from being attacked by the chlorine gas.

On the other hand, if the base metal chlorides, and the chloride of silver are extracted previous to the impregnation with chlorine, both metals—silver and gold—can be got out very close. On this fact is based O. Hofmann's gold and silver chlorination process, by which he successfully treated the gold and silver-bearing sulphurets of the Colorado No. 2, G. & S. M. Co., at Monitor, Alpine county, Cal.

The ore of Colorado No. 2, better known by the name "Tarshish mine," as it comes from the mine, is poor, assaying in average from seven to nine dollars per ton, but the gangue, being decomposed feldspar, causes the ore to be soft and easily crushed, and is by means of Frue's concentrators very high concentrated. The concentrated sulphurets consist of iron pyrites, silver glance, silver copper glance, fahlore, ruby silver, zinchenide and galena. The value of the concentration varies a great deal, ranging from \$250 to \$1,700 per ton, with over 40% of the value in gold, which is not free in the ore. The average value of five months' run proved to be \$564 per ton—\$333.19 in silver and \$230.84 in gold.

The operations of the process are the following:

1. The roasting.—The concentrated sulphurets are subjected to a chloridizing roasting in a reverberatory furnace. These furnaces, although old-fashioned stirring furnaces, are considered by Hofmann preferable for this class of ores to any mechanical furnace in use, especially to the continuous discharging ones. Those concentrated sulphurets require a very perfect roasting, and the furnaces, with continuous discharge, do not give time enough for very high sulphureted ore to become thoroughly desulphurized. Such high-grade ores require close attention, and the process must be under perfect control of the roaster. However, it does not take near as much time as required by Plattner's ore gold chlorination.

After the ore has been roasted, it is spread on the cooling floor and sifted, when cold, through a sieve of ten to fourteen meshes to the running inch. The sulphurets are heavy enough after roasting to make very little dust during the sifting, so that the inconvenient moistening can be obviated. The lumps are saved till a larger amount accumulates, they are then pulverized in a dry battery and slightly roasted.

2. Leaching of base metals.—The roasted and sifted ore is charged into tanks with filter bottom, in quantities from two and a half to three tons, and leached with water to extract all soluble base chlorides. The water, if saturated with those base chlorides and some salt, of which generally some is left in the ore undecomposed after roasting, acts on the chloride of silver like a concentrated brine, dissolving the same. To prevent the escape of this dissolved part of silver, Hofmann does not admit the water from above the ore as is usually done, but from below the filter-bottom, which, by means of a slight pressure, is forced to ascend through the ore to the top of the vat. In this way the concentrated solution accumulates above the ore, and in diluting the same by a stream of water and permitting the solution to flow out through the filter-bottom, the chloride of silver is precipitated on and through the ore, which is then extracted with the balance of the silver. This operation affects the fineness of the bullion somewhat, if there is a considerable amount of lead in the ore, but not materially. The bullion of Colorado No. 2 has by this process a fineness of 957.

3. Leaching of the silver.—This is done as usually by leaching the ore with a solution of hyposulphite of lime, and precipitating the silver with polysulphide of calcium. The hyposulphite dissolves more or less gold, so that the bullion of Colorado No. 2 contains from two to ten thousandths of gold.

4. Second leaching with water.—After the silver has been extracted, the solution of the hyposulphite is allowed to run out till it disappears under the surface of the ore, when clear water is introduced again, in order to displace all solution. The desilvered ore is then removed from the tank to a dry kiln, where it is left for a time till the surplus water has evaporated. After this, it is charged back into the tank still moist. This second handling and drying cannot be avoided, as the ore after leaching is too wet to permit of a free passage of the chlorine gas, but if the works are arranged properly, this partial drying causes neither much delay nor much expense.

5. Gold extraction.—The gold in the ore is

now in metallic condition, and very bright and clean, permitting a very close extraction. The rim of the tank is provided with a groove, which is open towards the inside, two and a half inches deep and one and a half inches wide. In this groove fits the cover of the tank, leaving, however, a play of one-eighth of an inch around the circumference. The cover being made of one-inch boards, the staves of the tank will project one and a half inches above the cover. This arrangement serves in two ways—first, it facilitates the operation to make the cover air-tight with clay, and, second, it enables the chlorinator to keep a sheet of water one inch thick on the top of the cover, thus making the cover perfectly air-tight and preventing the escape of gas into the working-room during the time of charging the tank with water for the purpose of extracting the gold. The cover is, furthermore, provided with two pieces of one and a fourth-inch gas pipe, six inches long, and a square opening six by six inches. During the time of the impregnation of the ore with gas, these pipes are closed with balls of clay. As soon as the charge is ready for the extraction of the gold, these balls are removed and one of the pipes is connected with the hose of the water-tank, while the other by means of a hose either with another tank already prepared for chloridizing, or with the ash-pit of the roasting furnace. This is done to utilize the surplus of chlorine gas, and to protect the workmen from the very injurious effect of the same. Care must be taken to have sacks placed on the top of the ore right under the water pipe, and kept in place by two bricks to prevent the stream of water working into the ore. The square opening serves for examining the progress of the gas in the ore, and can be closed air-tight by a good fitting cover and clay.

The chlorine gas is generated in a leaden gas generator, which is not heated, as usual, by direct application of fire, but by steam. For this purpose the generator is placed into a tight-fitting box, leaving a space of two inches around the side and bottom for the circulation of steam. The rim and cover are kept outside the box. The steam enters on one side through a half-inch pipe, while the other side of the box is provided with a one-inch exhaust pipe and an outlet for the water.

Wherever steam can be had in a chlorination work, this arrangement will prove very convenient and useful. The operator has the temperature entirely under his control. The least turn on the valve increases or decreases the heat, and, of course, regulates the generation of gas. The discharge pipe of the generator projects a short way out of the box. On this pipe is fastened a piece of hose about two feet long, which can be closed with a thumb-screw clamp. The hose lies in a covered trough, which leads outside of the gas-house. In discharging the generator a small stream of water is permitted to flow through the funnel into the generator, by which the gas is forced through its usual outlet into one of the tanks. When the generator is filled, the stirrer is set in motion and the thumbscrew on the hose loosened. In this way the generator can be discharged without molesting or injuring the men. The cover of the generator is closed tightly with clay and only removed in case of repair.

The gas is conducted through a leaden pipe intersected with rubber hose alongside and in front of the tanks, almost in the same height as the top of them. By means of a T and rubber hose, each tank is connected with the main pipe and can be disconnected by the use of a thumb-screw clamp. The pipe through which the gas enters the tank is independent from that one through which the solution discharges. It is placed higher and as close to the false bottom as possible.

After the gas has been the proper time in contact with the ore, the gold is extracted by water and precipitated in the usual way with sulphate of iron. The gold obtained is of extreme fineness, varying from 970 to 997 thousandths.

In treating very rich ores containing say \$700 to \$800 gold per ton, the solution carrying out the gold is of a very lustrous yellow color, and the precipitated gold accumulates on the bottom in spongy lumps of great specific gravity, some of them showing scales of bright gold, which under the microscope might prove to be crystallized gold. There is but very little more time used in leaching rich gold ore than poor.

If the ore is copperous, considerable copper will be carried out with the gold solution, coloring the same green. In order to save the copper, the solution, after the gold has been precipitated and settled, is decanted into the copper tanks. But before doing this it is advisable to draw the solution first into a second gold tank, in order to catch the gold which should accidentally be carried off with the stream, and to leave it there for some time to let the gold settle again.

Results.

To ascertain the working result of this process the concentrated raw sulphurets of the Colorado No. 2 obtained each day had carefully been weighed and assayed during a period of five months. The average value of these concentrations, as mentioned above, had been during said five months \$564 per ton, with over 40 % in gold.

The total value of the bullion shipped at the end of this period, compared with the net value of the raw sulphurets worked during the same time, showed the actual working result to be silver, 96%, gold 95%.

The Main Triangulation of the U. S. Geodetic Survey.

The following is a synopsis of Prof. Davidson's lecture, delivered in the Independent Church last Sunday evening, Dec. 14th. It was listened to by a large audience, and was remarkably well received.

The work of triangulation across the continent, being carried on by the United States Coast and Geodetic Survey parties, has developed many interesting facts. The questions which arose in this survey have great usefulness. It not only connects the work of the Coast Survey on the opposite coasts and gives the exact difference of longitude, but it establishes a series of lines, points, etc., across the continent. These points are given by the Government to the different States as points to start State surveys, and these give standards for all measurements in the country. This is a decided advantage over our present custom, where there are thirty-eight systems for the thirty-eight States.

During the past summer, Prof. George Davidson has been engaged in this work in the high Sierra, and at a recent meeting of the California Academy of Sciences he explained the method of triangulation which is carried on.

In carrying forward the net-work of triangulation, it has been considered necessary to establish unusually long lines, much longer than any ever laid out in Europe or India. It was a question in the minds of many whether the work could be carried forward with greater accuracy on this account. It was also a question of economy.

In 1872 Prof. Davidson made examinations upon the feasibility of observing long lines from the Coast range to the Sierra Nevada in one leap. In 1876 he occupied Mt. Diablo and Mt. Helena as the fundamental line from the Coast range, and this year he occupied two stations in the Sierra Nevada.

The original base line, in Yolo county, 11 miles in length, will be the longest in the world. This year the heliostopes were observed over

Archer's Invalid Bed.

longer lines than in 1876, and under favorable atmospheric conditions the image of the sun, reflected by a seven-inch heliostope, was seen at 160 miles with the unassisted eye. With the telescope these images, looking like stars, are seen through even the thick smoke of the Sacramento valley; and upon one occasion the heliostope was seen on Mt. Shasta at 169 miles distant, when Lassen Peak at 96 miles could not be seen on account of smoke and haze. The longest line observed upon was 192 miles—from Mt. Shasta to Mt. Helena.

It is found at these great heights that the atmospheric disturbances arising from irregularities in refraction are much less than at less elevations.

The horizontal angles are measured with a 20-inch theodolite with fine telescope, and with microscope micrometers for reading the circle. To correct for systematic errors of graduation, the circle is placed in 23 different positions, and thus measurements start from that many zeros.

To obtain the true bearings of the lines of the triangulation diverging from a given station, observations are made upon a close circum-polar star whose azimuth is computed; these are connected with a night mark, and subsequently this mark is referred to all the lines, whose true bearings thus become known.

The latitude and longitude of any given station is determined, and by proper formulae the latitude and longitude of every station in the network of triangles is computed, and the true direction of every line.

There are several peculiar phenomena in using the signals at these high stations. The observer, for instance, is at Mt. Round Top. At other stations are men with three-inch mirrors for lines of 60 to 70 miles, eight-inch mirrors for 160 miles, etc. One of these men directs the rays of the sun to a given point by means of his mirror, and these rays appear to those on Round Top as minute points. The beam reflected is about one hundred and twenty-five millionths of the sun's rays. The signal would be one-thirtieth of a second in diameter, too small to be seen by any ordinary telescope. On account of the disturbance of the atmosphere, the signal is enlarged, and the smallest diameter observed is one or one and a half seconds, or about the same as a star of the fifth or sixth magnitude. The image when smallest would be completely covered by the spider lines of the smallest spider.

When the atmosphere is much disturbed, the signals appear remarkably enlarged, and instead

of a variable speck, become 30 or 40 seconds in diameter and appear as spurious disks in the telescope. It takes skill to find the center of an object so large. At ordinary distances and at ordinary times the signals appear as a little bright speck, sometimes sparkling and generally reddish.

Over these great lines when the signals have passed through a stratum of air of varying density they have no longer the homogeneous light of the sun's beams, but this mass of air decomposes the rays as a prism would do. The light is decomposed into a spectrum, so that the signal shows as a vertical column of red, yellow and green, and not as a single spot.

To determine the position of Mt. Shasta was a very difficult job, on account of the difficulties of ascending and living there. On Shasta the rarification of the atmosphere makes it excessively oppressive. Only one of Mr. Colonna's party beside himself was able to stand it. This is the highest station to which an instrument has been carried—14,440 feet. From here Mr. Colonna observed upon the heliostope at Mt. Helena, a distance of 192 miles, and the longest ever observed upon.

The quadrilateral to connect Algiers with Spain contains a line 188 miles, and they have been several years preparing for the work. The mountains are invisible a great time in the summer on account of the haze, but in the fall and winter can be seen. Instead of holding placing men at stations to begin on the same day, each station is occupied to determine its latitude and longitude, and then the respective bearings of the stations are computed. Then a signal man is sent to the station to work on a given direction.

In the work of the U. S. Survey, however, great time was saved. The men go to a station, the instrument is directed to it, and the bearing obtained immediately. The work shows a rapidity of execution and progress having no counterpart.

Spring Tooth Harrow.

The accompanying cut represents an entirely new departure in the line of harrows. Its sale in the East has been unprecedented, and after

Batchelor's Spring Tooth Harrow.

three years of trial it is now in general use in the Eastern States and Canada. It is being introduced on this coast by Van Gelder, Batchelor & Co., 902 K street, Sacramento.

The teeth (see engraving) are nearly four feet long by two inches wide, and shaped like a rake tooth. They cut the soil instead of packing it, yield to anything solid instead of jerking the team, and lift the clods and grass to the surface, leaving mellow dirt about the seed. The depth of its work is controlled by moving the teeth. It is as thoroughly under control as a plow, and can be set to run from one to eight inches in depth. By turning it upside down, it can be moved about as well as a sled. The teeth stand so far from the frame that it seldom clogs. Their oscillating motion breaks more of the clods than other harrows, and shakes the dirt from the weeds, leaving them upon the surface with roots exposed. It cuts weeds instead of sliding around them. It cultivates the earth as thoroughly at the edge as at the center of its work; hence, there is no more necessity of lapping than with a plow. It cuts down elevations and fills depressions better than any other implement, thus saving the wear of mowers and other machines that follow.

WORKING MINES.—Under this heading the *Phoenix Journal* says: The sooner our people are made cognizant of the fact that mines are to be worked—not merely sold—the sooner will our chief industry and principal source of wealth rise to the importance that is properly due it. In California, Nevada and Colorado, for a long time, mines were chiefly worked with a view to speculation, rather than as a legitimate income to the owners. Mines were made to pay a dividend or submit to assessment as it was desired to make the stock go up or down. Mining superintendents worked under telegraphic instructions from New York or San Francisco, much as a train is run on a railroad by the "train dispatcher." Mines not on the stock board were not worked with a view to making them productive, but to make as large a hole as possible to sell some one else. Now, however, mining is being prosecuted, as we said in a recent article, as a means of money-making legitimately. Mines are now regarded as valuable for what they are actually worth when measured by the daily or monthly results in bona fide production.

Archer's Patent Invalid Bed.

Mr. James H. Archer, of this city, has recently patented through the Mining and Scientific Press Patent Agency, an improved invalid bed, of which we give an illustration on this page. By certain mechanical attachments to the bedstead, it may be elevated, tilted or adjusted to accommodate the invalid.

A represents the bedstead of the ordinary type, to which the bed bottom, made in a peculiar manner, is adapted. The side frames of the bed bottom are hinged as shown at a, as to form the bed bottom into two parts B, C, the head part, B, being somewhat larger than the lower or foot part. A supplemental leaf, as shown, is hinged to the side frames of the bottom as shown at b, so it may be used for elevating the patient's head.

At each corner of the bedstead is a folding adjustable standard, E, pivoted to the bedstead, so as to fold down out of the way when desired.

On the upper end of each standard are pulleys, d, e, and near the lower ends of each, attached to the bed frame, are the leading pulleys, f, those at the head being double.

On the back of the head board is a roller, F, with a ratchet, s, and pawl, g, at one end, and a gear, h, and pinion, i, at the other; a crank, j, being used to rotate the roller. Attached to this roller at opposite ends are cords for raising the bed bottom.

The cords, K, for raising the corners of the head end, lead from the roller down under the leading pulleys, f, and then over the lower pulleys, d, and over the upper pulley, e, through and over the upper pulley, e, and then down to the corners of the bed bottom.

The cords, K', lead from the rollers down under the leading pulleys, f, lengthwise the bed to the corresponding ones at the other end of the bed; thence upward between the rollers, d, e, and over e down to the foot corners of the bed bottom.

At each corner of the bed bottom is a curved link or hook, l, with which the knotted end of the cord will engage. By turning the crank therefore, the cords leading through the pulleys as described, will raise the bed bottom up by the corners to any desired height and the ratchet and pawl will prevent its lowering and hold it in place. The cords at either end or side may be disengaged and only one end or side raised when desired.

On the upper ends of the supplemental hinged leaf are placed links or hooks, m, into which the knotted ends of the head cords, K, may be caught, so that this supplemental leaf may be raised to any angle or inclination desired by the patient.

Corresponding hooks, n, are on the part, C, of the bed bottom and by placing the knotted ends of the cords, K', on these hooks, the lower end or foot of the part, C, may be dropped so it will set at an angle to the part, B, and still be retained by the foot-cords, K. This part may be more or less elevated for raising the knees of the patient.

Clamps, G, having set-screws, o, are arranged at the corners of the bed to keep the hinged standards in an upright position, and when desired by removing the set-screws, the standards may be folded down out of sight and the crank and roller may also be removed.

The bed bottom is intended to be placed on top of the mattress, and heavy canvas or webbing is used in its construction.

A sitting position may be maintained by raising the supplemental leaf by means of the cords, and also raising the part C by its hooks, when the part C and leaf will be at an angle.

When it is desired to raise the upper portion of the body from the hips, the supplemental leaf only may be elevated.

Either side may be raised by detaching the ropes on one side and raising the other, so the patient may easily be removed from the bed, or he more readily turned over.

For persons afflicted with rheumatism, when head and feet are both elevated very high, the foot of the bed may be raised up as desired and the supplemental leaf also, and the bed bottom assume an U shape, so the bed will touch all parts of the back and lower limbs.

The upper ends of the standards, above the pulleys, are extended and holes, p, formed through them, through which the cords may be passed for tying to the corners of the sheet, so as to sustain the patient when the sheets are to be changed and bedding removed. In order to do this, the bed bottom is raised up by the roller and cords to its highest point on the standards. Then by reversing the rollers the bed bottom, B, C, will be lowered down, and the patient be left suspended in the sheet until the bedding can be changed. The bed bottom is then raised up to the patient, the corners of the sheet released, and the patient is lowered to the desired position again. The side of the bed is then raised, the patient is turned, and the soiled sheet, on which he has been suspended, is removed. In this way the bedding is changed without inconvenience to the patient, and the operation may be rapidly performed.

The bed bottom may be raised half way up at any time, and air allowed to circulate under it in warm weather. When suspended in this way, persons may rock themselves by pushing with the foot against the foot-board, or the bed bottom may be rocked to and fro, to put a child to sleep, the same as in a hammock; the bed is therefore adapted to persons in good health who wish an easy position as well as it is to invalids.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick-silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.
Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also contains throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Pate's process, etc. He also describes the method of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Crocker's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Nolce's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous invention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tallies and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

TO APPEAR SHORTLY.

Crimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. Etc. Illustrated by EDWARD CRIMSHAW.

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small Hand Saws, Miter, Hog, Drag, Circular, Circular and Band Saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, iron, ivory, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, \$1.50. Orders for first edition received now.

CLAXTON, REMSEN & RAFFELFINGER, Publishers, 624, 626, 628 Market St., Philadelphia.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS is called to the new work by JOHN A. CHURCH, E. M. Ph. D., on "The Comstock Lode, Its Formation and History." This very exhaustive treatise on this famous lode is fully illustrated with diagrams and colored charts showing sections, ore bodies, etc., and will be of great interest and permanent value for reference. DEWEY & Co., Publishers of the MINING AND SCIENTIFIC PRESS, are sole agents for the sale of the work. Mr. E. M. SLEAVEL will act as their agent, and call on Mining Engineers and those interested in the great lode, with a copy of the book for their inspection.

507 Mechanical Movements.

Every mechanic should have a copy of Brown's 507 Mechanical Movements. Illustrated, described, inventoried, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$1, (post paid).

The Explorers' and Assayers' Companion.

(THIRD EDITION.)
438 octavo pages, bound in library or pocket size. Price, \$6 From all booksellers or direct from the author,

Fine Engraving.

The Engraving Bureau belonging to the office of this journal is prepared to design and engrave all kinds of Wood Cuts for illustrating newspapers, books, catalogues, cards, circulars, advertisements, labels, badges, seals, etc., in the best style of the art. Our portraits and illustrations of machinery, buildings and landscapes, are superior. Good engravings can be made from paintings, lithographs, steel and copper plate prints, photographs, models, patent office or other drawings. We have a photographic department and the best of machinery for producing accurate and perfect work at the lowest prices. Original maps, charts, and diagrams are made by our NEW PHOTO-RELIEF Process at greatly reduced rates. By the same process copies can be cheaply and quickly produced of printed cuts, in fac simile, or they can be enlarged or reduced with equal facility.

Any hand writing in perfectly black ink on clear white paper for manuscript letters or circulars, will be accurately reproduced in metal plates suitable for common printing. Also, fac simile signatures, monograms, sheet music, etc. We excel in trade cuts and matched plates for combination color printing. With a large business, long established, and every facility for improvement, we can guarantee more than ordinary satisfaction to all of our patrons. All interested are invited to send for or call and see specimens and obtain prices.

Orders for electrotypes, stereotypes, steel and copper plates, lithographing, stamps and seal presses executed at low rates.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in subdivisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

LEE D. CRAIG,

Notary Public

—AND—

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of PHOSPHATE SOAP, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use PHOSPHATE SOAP.

For chapped hands the constant use of PHOSPHATE SOAP will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879,

To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your PHOSPHATE SOAP as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.

SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:

I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, Pruritus, the other an Eczema. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.

126 O'Farrell St.

To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:

I have tried your PHOSPHATE SOAP, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. HENRY H. LYNCH,

515 Haight street.

The genuine merits of PHOSPHATE SOAP and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Channel Street, off foot of Fourth, San Francisco, Cal.

Highest price paid for Sulphurets, Arseniurets, Tellurides and Gold Ores generally.

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Ad-
justed than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

A. T. DEWEY.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

AN ENGINEER.

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouing or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

PATENT

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.
